Native of the Alps of Europe.

4. *Root* annual. *Stems* about three inches high, one to five, or more from the ſame root in a rich ſoil; ſmooth after flowering, but hairy when young. *Leaves* ovate-lanceolate, narrower at the baſe; ſome entire, others ſubſerrate, ſpreading on the ground, ſomewhat ſcabrous, hirſute, ſome of the hairs bifurcate, others trifurcate. *Peduncles* alternate, bearing one flower only. Leaflets of the *calyx* obtuſe and ſomewhat hairy. *Corolla* petals white, twice the length of the calyx, two-parted. *Filaments* bending forward; the four longer ones the height of the piſtil. It is difficult to find the full complement of ſtamens when the flower is fully expanded, as they drop when the germ begins to enlarge. *Silicle* terminated by a ſhort blunt point. *Seeds* ovate, brown, fixed to the edge of the partition [h]: from three to ſix in a cell, according to Scopoli, but ſometimes as many as twenty-four [i]. By theſe it propagates itſelf prodigiouſly, and is a weed hardly to be eradicated in dry paſtures, gravel-walks of gardens, *&c.*

Linneus obſerves that the flowers hang down in the night and in wet weather: that in Smoland they ſow Rie when this plant is in bloſſom; and that in dry ſoils whole fields are covered with the flowers early in the ſpring. With us it is common on walls, dry banks, fields, and paſtures, flowering in march and april, or earlier if the weather be mild.—In ſome countries abundance of this little plant is ſuppoſed to prognoſticate dearneſs of corn; which may have ſome foundation, as a wet ſeaſon produces a great crop of this little weed, which according to ſome is agreeable to ſheep [k].

Gerarde calls it Whiteblowe, or Whitlowe-graſſe, or Naile woort.

This ſmall plant may ſerve as an index of the difference of climates; for in Sweden it flowers in the month of april; in Germany a month earlier; in England, Holland, and France in february; whilſt in Sicily it flowers all the winter.]

5. This is a perennial plant, ſeldom more than two inches high; it has a ſhrubby ſtalk, dividing into many ſmall heads. Leaves ſmall; the lower ones have five ſhort narrow lobes, the upper have but three. The flowers come out in cluſters, ſitting cloſe to the leaves: they are of a bright purple colour, and appear early in the ſpring.

[Root creeping, putting out erect branching ſhoots, which at the end bear thick ſhining ſtiffiſh ſpreading leaves, half-three-lobed, narrowed at the baſe into a ſort of half-embracing erect petiole, marked with three lines; the lobes ſpreading oblong ſharpiſh, ciliate at the tip and interruptedly on the edge. Scape round erect ſcarce half an inch high, from the centre of the branchlet, five-flowered; and from the ſame point, at the ſides of it, ſpring two other branchlets deſtined to bear flowers the following year. The proper peduncles higher than the ſcape form a corymb. Calyx greeniſh purple. Petals roundiſh, large, flat, ſpreading much, quite entire, veined, purple, on ſhort claws. Filaments purple. There is a roundiſh, large, bifid gland on each ſide within the ſhorter ſtamens. Style almoſt the length of the germ. Silicle obovate, compreſſed at top and bottom different ways. Seeds two [l].

Native of the mountains of Switzerland, in the

[a] Linn. mant. [b] Haller. [c] Scopoli. [d] Gouan. [e] Hort. kew. [f] Linn. mant. [g] Linn. ſyſt. [h] Curtis and Withering. [i] Gærtner. [k] Krocker. [l] Jacqu. vind.

Canton of Appenzel, Provence, Carniola, Auſtria, and Piedmont: flowering in may.

6. Root annual. Root-leaves entire at the baſe, toothed upwards. Leaves and ſtem hairy. Stem-leaves rather heart-ſhaped. Fruit-bearing pedunculs horizontal, longer than the ſilicles. Corollas pale yellow or white, with the petals ſlightly emarginate. Silicles exactly elliptic, ending in a ſhort blunt knob. Seeds reddiſh brown [a].]

It riſes with an upright branching ſtalk about ten inches high. Leaves heart-ſhaped, indented, embracing. The ſtalks are terminated by looſe ſpikes of white flowers, which appear the beginning of may.

[Native of Sweden, Switzerland, Germany, South of France, Italy, in fiſſures of rocks. Mr. Ray found it near Montpellier, and between Lucca and Piſa, in hedges. With us, in Derbyſhire, Yorkſhire, and Weſtmoreland. Common about Malham.

β. The *wood* variety being ſowed with the *muralis* in a garden, they became ſo alike as not to be diſtinguiſhed by any means, the yellow flowers becoming white [b].

7. Reſembles *D. incana* very much, but the ſtem is naked with a ſingle lanceolate leaf in the middle of it. Petals white emarginate. Silicles more ſmooth and ovate; with the peduncles only half their length; but ſubſeſſile [c].

Perennial. Root-leaves elliptic, ſmooth, ciliate, tongue-ſhaped: ſtem-leaves ſeſſile ovate-acuminate, having only two teeth. Silicles ſmooth, like thoſe of *D. verna*. It varies in the leaves, which are ſometimes ſmooth and ciliate only about the edge, or hairy all over and hoary; ſometimes toothed, at others quite entire [d].

It differs from *D. nemoroſa* (n. 6. β.) in having a perennial root, entire leaves, and white flowers [e].

It has very much the air of *D. verna*; the leaves ſhorter, covered with a ſhort down, and ſcarcely toothed. Oftentimes, but not always, there is one leaf on the ſtem, and ſometimes two. Scapes flexuoſe, three inches high and more. Peduncles ſhorter than in the common ſort. Calyx ſubhirſute, browniſh. Petals entire. Silicles narrower than in *D. verna*, otherwiſe like them, terminated by the ſhort ſtyle with a headed ſtigma. Seeds ovate, acuminate [f].

Native of Lapland, Denmark, Provence, Switzerland, Sileſia, Auſtria, Piedmont, in the fiſſures of rocks: flowering in may. Mr. Dickſon has found the Draba ſtellata or hirta of Jacquin in Scotland, on Ben Lawers.

Jacquin, in his Obſervations, ſays that his *ſtellata* is the *hirta* of Linneus, but that in the Auſtrian plants the ſilicles are uſually ſtraight, very ſeldom oblique. Though he gave up his *ſtellata* as a ſpecies, yet it ſeems to be different from Linneus's *hirta* [g]. He thus deſcribes it.—This little plant has the habit and ſize of *D. pyrenaica*. Leaves obverſely lanceolate, blunt, attenuated at the baſe into a ſort of petiole half embracing the ſtalk; they are thick, either quite entire, or with a ſingle tooth on each ſide, ſeldom more, ciliate and having on both ſides white hairs radiating like a ſtar at top, more than in *Leontodon biſpidum*. Scape round, erect, with ſimilar hairs at bottom, but more thinly diſpoſed, at top more naked, there is a ſingle ſeſſile ſubovate toothed leaf on it, ſometimes two, and ſometimes ſo low as to be loſt among the root-leaves. Corymb terminating, made up of about ſeven longiſh peduncles, the lower ones not reaching above the ſcape. Calyx yellowiſh. Petals milk-white, roundiſh-obovate, entire, flat, very wide and ſpreading, twice as long as the calyx, on a very ſhort claw. Stamens whitiſh, the length of the calyx. Gland within each ſhorter filament. Style ſhort. Silicle oblong [h].

8. Root fuſiform, perennial. Root-leaves forming roſes, lanceolate, bluntiſh, quite entire, flat, ſhining, ſmooth, firm, ciliate with diſtant hairs. Stems from the centre of the roſes, erect, undivided, ſlender, an inch high, naked: they have one or two ſeſſile, lanceolate, ſmooth, entire leaves on them, villoſe-ciliate on the edge. Raceme terminating, few-flowered. Flowers from five to eight, pedicelled. Calycine leaflets naked, half the length of the petals, green. Petals ſnowy-white, ſlightly emarginate. Filaments awl-ſhaped, white, with ovate, yellow anthers. Silicle naked. It has no ſcent.

Native of Carinthia [i].

9. Root biennial. Root-leaves very numerous, ſpreading like the flower of a roſe, lanceolate, tomentoſe and ſomewhat hairy, entire, acute. Stem a hand in height, ſtraight and ſtiff, hoary, cloathed with many leaves (frequently more than thirty), very like the root-leaves, but ſhorter, ſo that the uppermoſt are ovate, ſeſſile, and have a few teeth; on the lower part of the ſtem they are more crowded. Flowers in a ſmall terminating corymb: petals white, obſcurely emarginate. Silicles in a raceme, erect, ovate-oblong, oblique, twiſted in a direction contrary to the ſun's diurnal motion, compreſſed, naked; peduncles hoary, three times ſhorter than the ſilicles, ſtiff, approaching to the ſtem. It flowers with the Anemone [k].

Stems from five or ſix to nine inches in height, ſlightly tomentoſe, ſimple moſt commonly, but frequently branched, crooked.]

Mr. Miller ſays, that the upper part of the ſtalk puts out two or three ſhort branches, which are almoſt naked of leaves, as is alſo the upper part of the ſtalk.

[Leaves oval-lanceolate, a little hairy, the lower ſlightly the upper deeply toothed. Peduncles nearly as long as the ſilicles, which are lanceolate, ſmooth, twiſted, terminated by the blunt ſtigma [l].

Native of Lapland, Sweden, Denmark, Norway, Britain, as in Weſtmoreland, Yorkſhire about Settle, and near the ſummit of Ingleborough; Scotland, as in Iſla, Skye, &c. Wales in Caernarvonſhire. It flowers in may and june.]

PROPAGATION AND CULTURE.

1, 2, 3, 5. Theſe plants are eaſily propagated by parting the heads in autumn; for they ſhoot up to flower very early in the ſpring. They will thrive and flower annually, in a moiſt ſoil, and ſhady ſituation; and require no other culture but to be kept clean from weeds.

With reſpect to the reſt, if the ſeeds are ſown in autumn in a ſhady border, the plants will come up in the ſpring; or where the ſeeds are permitted to ſcatter, the plants will riſe without any trouble.

[Some of the ſpecies are proper to adorn rock-work, and they all proſper beſt in that ſituation.

Arborescent; leaves ensiform, acute; raceme terminating, erect, superdecompound.]

DESCRIPTIONS, &c.

1. This rises with a thick trunk nearly equal in size the whole length; the inner part very pithy, next to this a circle of strong fibres, and the outside soft; height twelve or fourteen feet, nearly of the same diameter the whole length, which is rarely more than eight or ten inches; circular marks or rings are left the whole length, where the leaves have fallen off. The top sustains a large head of these, coming out singly all round it; they are shaped like those of the common Iris, but are much longer, being often four or five feet in length, and an inch and half broad at their base, where they embrace the trunk, they lessen gradually and terminate in a point: these leaves are pliable, and hang down; they are entire, of a deep green, smooth on both surfaces. It has the habit of the Palms.

[The peduncles are furnished with a joint.—Crantz has made two genera out of this species, under the names of Oedera and Stöckia[a].

Native of the East Indies.]

Mr. Miller received a plant of it from the Cape Verd islands, and feeds from Madeira.

It is called Dragon-tree, because the inspissated juice becomes a red powder very like the eastern Dragon's blood.

[Cultivated in 1640, by Parkinson[b]; who sowed the seeds, but they did not abide the winter.

2. Stem shrubby, almost simple, eight feet high, erect, round, with close protuberant rings from the fallen leaves; these are quite entire, a foot and half in length, erect, smooth, on stem-clasping petioles, and of a dusky-red colour. Flowers red-purple, subterminating: spadix diffused; spathe long, awl-shaped, permanent: proper perianth trifid, cup-shaped, small, permanent. Corolla bell-shaped, six-parted, inferior; segments oblong, obtuse, spreading. Anthers sagittate, sharp and bifid at the end. Style awl-shaped, thick, trifid, equal to the stamens: stigmas simple. Berry red. The seed is usually abortive. It seems to approach the Palms[b].

In Chinese it is called *Tat-sio* or *Thet-tsiao*; and is planted in gardens both there and in Cochinchina.

Native of China. Introduced 1771, by Benjamin Torin, Esq. It flowers in march and april[c].

3. Found at the Cape of Good Hope, by Thunberg[d].

4. Leaves almost like those of *Canna*. Raceme terminating, composed of a few branched racemes. Pedicels alternate, solitary, shorter than the flower, surrounded at the base by an obtuse glume. It is a hard tree.

Native of the East Indies[e], and the Society isles[e].

5. Leaves ensiform-lanceolate, nerveless, keeled underneath, petioled. Scape or stem branching, panicled, with two coloured leafleta at the origin of the branches[b].

Root perennial, horizontal, creeping, somewhat woody, odoriferous, simple. Root-leaves heaped, thick, striated, shining, reflex, a foot long. Scape three feet high, leafy at bottom, naked at top, round, slender, declining; flowers terminating, subumbelled. Corolla bell-shaped, spreading; petals lanceolate, blue on the outside, white within, small. Filaments spreading, dilated at the base. Berry roundish, blue, three-grooved, containing many minute seeds[b].

Gærtner describes the fruit as a superior subglobular berry, of a violet purple colour, fleshy, but when ripe drying up to a thin, obovate crust, marked with three grooves, gibbous at the seeds, having three cells but no valves; partitions membranaceous drawn from the grooves to the axis. Seeds rounded kidney-form, or beaked at the navel, compressed like a lens with a conical boss in the middle on both sides, very smooth, shining and black; two in each cell; fixed to the inner angle. Embryo monocotyledonous, roundish, slender, placed near the navel. This species perhaps more properly belongs to the genus *Medeola*, for it differs remarkably from *D. Draco* in the fruit. The synonym of Rumphius is doubtful, for he attributes nine seeds to his Gladiolus.—Cultivated 1759, by Mr. Miller[b].

Native of the East Indies, and Cochinchina.—Loureiro says, that if he had followed his own opinion, he should rather have referred this plant to the genus Ornithogalum.

6, 7, 8, 9. Found at the Cape of Good Hope by Thunberg[d].—Dracæna Medeoloides and Medeola asparagoides are probably one and the same plant[b].

10. Stature of *Anthericum Phalangium*. Leaves like those of grass, very much streaked, a span in

length.

length. Scape ſcarcely longer than the leaves. Four or five flowers at each tooth of the raceme, on pedicels ſhorter than the flower itſelf, coming out from a kind of obſcure glume.

Native of Aſia [a].

11. Native of the iſland of Bourbon. Introduced 1776, by Monſ. Richard. It flowers in april [a].

12. Native of Newfoundland, Hudſon's Bay, and Canada. Introduced 1778, by Dan. Charles Solander, L. L. D. It flowers in june [a].

13. Native of New Zealand, in woods on the coaſt of Duſky Bay.

Trunk round, full of ſmall chinks, undivided, leafy at top, from ſix to nine feet high. Leaves half-ſtem-claſping, imbricate at the baſe, quite entire, ſpreading, ſtriated, bright green, two feet long and a hand broad. Raceme apparently lateral, but perhaps this was owing to the next ſet of leaves deſtined for the enſuing year coming out; it is ovate, nodding, with the partial racemes digeſted into a cylindric thyrſoid form. Univerſal peduncle two or three feet long, round, even, herbaceous, an inch and half in diameter: partial peduncles a ſpan long, approximating, from erect ſpreading, round, even, having a lanceolate leaf at the baſe, the length of the peduncle; they come out ſcatteringly on every ſide from the univerſal peduncle. Pedicels one-flowered, very ſhort, horizontal. Bractes at the baſe of the pedicel two, very ſmall, lanceolate, acute, concave. Petals ſubreflex. Germ ſuperior. Style ſhort. Berry globular, blue, marked above with three hollow dots, mucronate with the permanent ſtyle, having about ſeven ſeeds in each cell, involved in an aril or membrane, ſo as to appear only one; they are black, ſmooth, ſemilunar and three-ſided. The generic character conſtructed from the firſt ſpecies does not agree very well with this or *D. terminalis*, which have many ſeeds in their berries. Perhaps the berry of the firſt alſo may be involved in an aril, and this may conſtitute the eſſential diſference between *Aſparagus* and *Dracæna*.

The berries of this ſpecies are eaten by the natives, they are ripe in may, that is at the beginning of their winter. The young leaves, or rather the hybernacle concealed among them, is an excellent ſalad; and this, together with Areca oleracea and ſapida, Apium graveolens or Smallage, Tetragonia halimifolia, Lepidium oleraceum and piſcidium, and Sonchus oleraceus or Sowthiſtle, was found to be of great ſervice to our circumnavigators in reſiſting the putrid ſcurvy.

14. Native of New Zealand [a].

Leaves crenate; root-leaves cordate, ſtem-leaves orbiculate ſeſſile; bractes acuminate-toothed.

13. Dracocephalum nutans. *Nodding Dragon's-head. Lin. ſpec* 831. *Reich.* 89. *hort. upſ.* 167. *n.* 2. *Gmel. ſib.* 3. 231. *t.* 49.
Bractes oblong ovate quite entire, corollas rather large nodding.

14. Dracocephalum thymiflorum. *Small-flowered D. Lin. ſpec.* 831. *Reich.* 90. *hort. upſ.* 167. *Gmel. ſib.* 3. 233. *t.* 50. *Gærtn. fruct.* 1. 319.
Bractes oblong quite entire, corollas ſcarcely larger than the calyx.

[15. Dracocephalum cochinchinense. *Lour. cochinch.* 371.
Flowers in ſpikes, bractes roundiſh acute, leaves ovate-lanceolate, quite entire.

DESCRIPTIONS, &c.

The ſpecies of this genus are moſtly herbaceous, ſome few however are underſhrubs. The ſtalks are ſquare; the leaves oppoſite in pairs. The flowers are either in whorls forming all together a ſpike at the end of the ſtalk, or axillary on one-flowered or many-flowered peduncles; they are ſupported by bractes, which are generally broad, and ſometimes ciliate; in the firſt ſpecies however they are narrow and very ſmall.]

1. This riſes with an upright ſtalk, near three feet high.[a] Leaves about three inches long, and half an inch broad, ſeſſile; they are uſually in pairs at each joint, but ſometimes there are three together. The flowers are purple, in terminating ſpikes, and make a pretty variety among other hardy plants. It is perennial, and flowers from july to ſeptember.

It is a native of North America, in woods, and by the ſides of rivers.

[Cultivated in 1683, by Mr. James Sutherland[a].

2. Allied to the firſt ſpecies, but inferior in point of beauty. It ſpreads more on the ground; its flowering ſtems are not altogether ſo upright, nor ſo tall; the leaves are broader, and the flowers in the ſpikes leſs numerous. It flowers in auguſt and ſeptember. Mr. Curtis received ſeeds of it from Philadelphia, collected at a conſiderable diſtance from that city, about the year 1786. And Mr. Watſon, nurſeryman at Iſlington, obtained the plant from Carolina, about the ſame period[b].]

3. This is a perennial plant, riſing with ſeveral ſtalks to the height of three feet or more, becoming woody at the lower part. Leaves at each joint, having three or five, oblong, pointed, ſerrate leaflets. The flowers come out in ſhort thick ſpikes on the top of the ſtalks; they are of a pale blue colour, and are produced from july to ſeptember.

[a] Hort. kew. [b] Curtis magaz.

[The leaves are on petioles from an inch to two inches in length, triangular, two of the angles and the joints moderately hairy. Leaves ſoft, wrinkled like thoſe of Mint, veined, moſtly ternate, the middle leaflet much longer than the other two; ſome of the lower ones have five leaflets, ſomewhat like thoſe of Hemp; each leaflet an inch wide, and two inches long, mucronate and toothed. (A plant which I have now before me, october 3, 1795, has not one leaf but what is ternate, but it is an old plant, and has loſt the lower leaves. The young petioles are quite white with hairs, on thoſe which are far advanced the hairs are diſtinct, and perpendicular to the petiole; the lower ſurface of the young leaves is alſo very hairy, but the upper ſurface is bald: the petioles are not triangular, but flat and channelled above, and convex beneath. Stiff pellucid hairs, or rather tender prickles, are thinly ſcattered along the angles of the ſtem, and there are thick tufts of long white hairs at the joints.) Spikes broadiſh, from an inch to two inches in length. Calyx long, ſtriated, (hairy, on a very ſhort pedicel.) Corolla fleſh-colour or pale purple, with white lines.

Native of the Canary iſlands, whence it was brought to Europe, by the name of *Permento de Tana*[c]. The old writers call it *Camphorofma* and *Cedronella*, and we *Balm of Gilead*, from its rich odour, on being gently rubbed.

It was deſcribed by Moriſon in 1690[d], and was cultivated in 1697, by the Dutcheſs of Beaufort[e].

4. Stems ſhrubby, decumbent. Leaves tranſverſely pinnatifid, obtuſe with remote lobes, on long petioles. The ſpike is like that of *Melampyrum arvenſe*. The bractes are lanceolate with briſtly teeth, and are often red. Corollas ſmall; ſtyles twice as long as the flowers.

Native of Jerkatſch, in Siberia[f].

5. Root perennial. Stems ſeveral, a long ſpan in length, with the joints an inch aſunder. Leaves like thoſe of common Hyſſop or Roſemary, moderately hoary underneath; from the axils of theſe come out branches with ſimilar leaves, but ſmaller, and flowers at the end, with rigid calyxes, and corollas of a very elegant blue-purple colour. Seeds oblong, angular, blackiſh[g].

Native of Siberia. Cultivated before 1699, by Mr. Jacob Bobart[h].]

6. Root perennial. Stalks hairy, a foot and half high, ſending out ſeveral ſide-branches. Leaves hairy, linear, cut into three parts. Flowers terminating in ſhort whorled ſpikes, with ſome very narrow leaves (bractes) under each whorl. Tube of the corolla longer and more equal than that of the next ſpecies, and the middle ſegment of the lower lip not ſo much reflexed.

[This is a beautiful plant and grows in Auſtria, where it was firſt obſerved by Cluſius. It varies according to its ſoil in point of number of ſtems, &c. The ſtems are annual, ſquariſh, and villoſe: the leaves oppoſite; hoary below, ſmooth and green above, and are deeply lobed or cut in a pinnatifid manner. The flowers are axillary on the upper part of the plant, commonly in pairs, ſometimes in threes; and are of a violet-purple colour, paler without[i].

Native of Auſtria and Hungary. Introduced 1788, by Joſ. Nich. de Jacquin, M. D.[k]—If ſo, it is not the ſame with Miller's or Amman's plant.]

7. Root perennial. Stems about two feet high with two ſmooth linear leaves at each joint, about an inch long, and one-eighth of an inch broad, with a deep furrow along the middle: at each joint, at the other ſides of the ſtem, come out two or three very narrow ſmall leaves of the ſame ſhape. The calyxes are cut into five ſegments at top, of which four are narrow and acute: and the fifth, which is on the upper ſide of the flower, is broader and

[c] Moriſon. [d] Linn. ſyſt. [e] Hort. kew. [f] Linn. ſpec.
[g] Moriſon. [h] Hort. kew. from Mor. [i] Jacquin.
[k] Hort. kew.

rounded at the point. The tube of the corolla is longer than the calyx, ſwelling and large at the chaps; the upper lip broad, erect and arched over the tube; the lower ſhorter, with two ſhort, erect ſide ſegments, but the middle ſegment is broad, rounded and indented at the point, and reflex. The flowers appear in june, and are of a fine blue colour.

[Stems numerous, a foot in height, with a branch from the axil of each leaf. The leaves are apt to contract their edges. Whorls on two branches, having about ſix flowers in each, on ſhort pedunculs. Theſe whorls on the topmoſt branches are continued into ſpikes. Corolla an inch long and hirſute; the wings of the chaps ovate and lanceolate; beard bifid, ſerrate, ſpotted. Anthers black; pollen white [t].

Native of Norway, Sweden, Switzerland, Siberia. Cultivated in 1758, by Mr. Miller [u].

This and the foregoing ſpecies, were ſeparated by Boerhaave, and made a diſtinct genus, under the name of *Ruyſchiana*, in honour of Dr. Ruyſch, who was profeſſor of anatomy and botany at Amſterdam.]

8. The ſtalks of this do not grow erect, like the preceding, but ſpread nearer to an horizontal poſition; they divide into ſeveral branches, which have a pair of large leaves at each joint, and four ſmaller, two on each ſide; they are ſmooth, have ſharp indentures on their edges, and ſtand erect. The flowers come out from the ſide of the ſtalks at the baſe of the leaves, two or three together on each ſide. Calyx purple, cut into five acute ſegments, three broad in the upper lip, two narrower in the lower. Upper lip of the corolla broad, indented at the point and erect; lower trifid, but the middle ſegment not ſo much reflexed as that of the preceding; and the whole of a paler blue.

[The chaps of the corolla are broad and almoſt inflated; the upper lip is compreſſed and bifid; the lower toothletted, and villoſe in front: the two upper ſtamens are hirſute at the baſe.

Native of Siberia [v].—Introduced in 1760, by Mr. James Gordon [w].

This, and all the foregoing ſpecies, are perennial. The third is marked in the Kew catalogue as biennial.]

9. This is an annual plant, riſing with branching ſtalks a foot and half high, with oblong leaves, deeply ſerrate on their edges. The flowers come out in whorls round the ſtalks at every joint; they are blue, and appear in july, continuing to the middle of auguſt. The ſeeds ripen in ſeptember. The plant has a ſtrong balſamic odour, which to ſome perſons is very agreeable.

Native of Moldavia. [Cultivated in 1596, by Gerarde.]

10. This has hoary ſtalks, a foot and half high, putting out two or three ſide branches, with hoary leaves near two inches long, and half an inch broad, a little indented on their edges; they are placed juſt under the whorls of flowers, which ſit cloſe to the ſtalk: the corolla is large, of a fine blue colour, and makes a pretty appearance among the hoary leaves. It flowers and ſeeds about the ſame time as the foregoing ſort, and is generally treated as an annual, but the roots will live two years in a dry ſoil. There is a variety with white flowers.

Diſcovered by Tournefort in the Levant.

[Cultivated in 1712 [y].]

11. This is an annual plant, about a foot high, ſending out two ſmall branches from the lower part. Leaves lanceolate, crenate, petioled. Flowers ſmall, purpliſh; coming out at the ſame time with the two foregoing.

Native of the Levant, whence Tournefort ſent the ſeeds to the royal garden at Paris.

[Cultivated in 1731 [z].

The fourth ſpecies of Miller ſeems not to differ from this.]

[t] Haller. [u] Hort. kew. [v] Linn. ſpec. [w] Hort. kew. [y] Ibid. [z] Ibid. from Mill. dict. edit. 1.

12. Root-leaves like thoſe of Betony, petioled, obtuſe, wrinkled, pubeſcent; ſtem-leaves almoſt wedge-ſhaped, rounded, very obtuſe, crenate-toothed. Bractes two on each ſide, very obtuſe, the length of the calyx; beſides two minute, lanceolate little bractes, belonging to the lateral flowers. [The bractes and floral leaves are ſomewhat of a violet colour [a].

The whorls have the flowers by threes on each ſide. Calyxes ſubpeduncled, five-cleft, the three upper teeth leſs divided. Corollas large, blue; the chaps much inflated, with a riſing ſtreak at the back on each ſide: upper lip bifid; lower trifid; the middle ſegment larger, dark-blue, reflex, bearded at the end. Anthers oblong.

Native of the Siberian alps.—That which was deſcribed in the *Species plantarum* is a mere variety of this [b]. Native of Siberia. Introduced in 1783, by Mr. John Bell [c].]

13. This alſo is annual. Stalks many, weak, about nine inches high, having at bottom ovate-lanceolate leaves about two inches long, and an inch and quarter broad, crenate, and on pretty long foot-ſtalks. The upper part of the ſtalks has ſmaller leaves, ſitting cloſe at the joints, and from theſe come out the flowers in whorls; they are of a deep blue colour, and hang down, appear at the ſame time with the preceding, and the ſeeds ripen in autumn.

Native of Siberia, whence the ſeeds were ſent to the Imperial garden at Peterſburgh. Dr. Amman ſent the ſeeds to Mr. Miller, who cultivated them before 1768.

14. The ſtalks of this riſe a foot and half high. The lower leaves are very like thoſe of Betony, and ſtand upon very long foot-ſtalks: the upper leaves are ſmall, and ſit cloſer to the ſtalks. The flowers come out in whorls at every joint, they are of a pale purple or blue colour, and being ſmall make little appearance.

[Seeds ſmall, ovate-oblong, ſlightly convex on one ſide, angular on the other, dark cheſtnut colour [d].

Native of Siberia. Cultivated by Mr. Miller in 1759 [e].

15. Stem herbaceous, ten inches high, erect, grooved, villoſe. Leaves villoſe, few. Flowers violet-coloured, in terminating ſpikes. Bractes many-flowered. Filaments hairy.

Native of Cochinchina [f].]

PROPAGATION AND CULTURE.

1. This will live in the open air, but requires a moiſt ſoil, or ſhould be duly watered in dry weather, otherwiſe the leaves will ſhrink, and the flowers make little appearance. It may be allowed a place in the ſhady borders of a garden, for it will not ramble, nor take up much room; and may be propagated by parting the roots in autumn.

[2. This, as well as the firſt, is a hardy perennial, multiplying conſiderably by its roots, which creep in ſome degree; it muſt be planted in a moiſt ſoil and ſhady ſituation [g].]

3. Balm of Gilead is uſually kept in the greenhouſe; but in mild winters the plants will live abroad in warm borders; and thoſe which are kept in pots will thrive much better when ſheltered under a frame than in a greenhouſe, where the plants are apt to draw up weak; for they ſhould have as much free air as poſſible in mild weather, and only require to be ſheltered from ſevere froſt. This may be propagated by ſeeds, which, if ſown in autumn, will more certainly grow, than thoſe which are ſown in the ſpring; but if theſe are ſown in pots, they muſt be ſheltered under a frame in the winter, and if the plants do not come up the ſame autumn, they will ariſe in the ſpring; but if the ſeeds are ſown in the full ground, it ſhould be in a warm border; and in hard froſt they ſhould be ſheltered, otherwiſe the young plants will be de-

[a] Linn. ſyſt. [b] Linn. ſuppl. [c] Hort. kew. [d] Gartner. [e] Hort. kew. [f] Loureiro. [g] Curtis magaz.

ſtroyed.

ſtroyed. The plants may alſo be propagated by cuttings; which, if planted in a ſhady border any time in ſummer, will very ſoon take root, and furniſh plenty of rooted plants.

6, 7, 8. Theſe plants are propagated by ſeed, which ſhould be ſown the latter end of march, in a bed of freſh light earth in an open expoſure, and in about five or ſix weeks after, the plants will appear, when they ſhould be carefully cleared from weeds; and if the ſeaſon ſhould prove dry, they muſt be refreſhed now and then with water, which will greatly promote their growth. When the plants are about two inches high, they ſhould be carefully tranſplanted into a bed or border of freſh, light, undunged earth, obſerving to ſhade them from the ſun until they have taken root, as alſo to refreſh them with water until they are well eſtabliſhed in this bed; after which time they will require no farther care, but to keep them conſtantly clear from weeds till michaelmas, when they are to be removed into the places where they are deſigned to remain for good.

When the plants are firſt tranſplanted from the ſeed-bed into the nurſery-bed, they ſhould be planted about ſix inches aſunder every way, which will be ſufficient room for them the firſt ſeaſon; and this will admit of the hoe to come between the plants to deſtroy the weeds, which is by much a better method than pulling out the weeds by hand, and is much ſooner performed. For as the hoe ſtirs the ground between the plants, it not only cuts down the weeds which were up and viſible, but alſo deſtroys all thoſe whoſe ſeeds were ſprouted, and would have ſoon after appeared; ſo that one hoeing, if well performed, and in dry weather, will more effectually deſtroy the weeds than two hand-weedings would do, were they performed ever ſo carefully; beſides, the ſtirring the ground is of great ſervice to the plants.

At michaelmas, when the plants are tranſplanted for good, they ſhould be carefully taken up with balls of earth to their roots; and they muſt be planted in the middle of the borders in the pleaſure-garden, in freſh light earth, intermixing them with other hardy plants of the ſame growth, where they will make a pretty appearance when they are in flower, and will continue three or four years; and in ſome poor ſtony ſoils I have known the roots live ſix or ſeven years, but theſe did not produce ſo large ſpikes of flowers as thoſe which were younger and more vigorous plants. Therefore, as theſe plants do not continue many years, it will be proper to raiſe a ſupply of young plants to ſucceed them, for the old plants will produce ſeeds plentifully, which are ripe the latter end of auguſt or the beginning of ſeptember, when they ſhould be gathered in dry weather, and kept in a warm dry room till the time for ſowing them.

9—14. All theſe ſorts may be propagated by ſeeds, which may be ſown either in the ſpring or autumn in ſmall patches upon the borders where they are to remain. When the plants come up, they ſhould be thinned where they grow too near together, and kept clear from weeds.

Leaves perforated, ſtem climbing.]

DESCRIPTIONS, *&c.*

1. This has a large knobbed irregular root, covered with a rugged brown ſkin. The ſtalk riſes about a foot high, is ſmooth, and of a purple colour, full of ſharp protuberancies of different colours, ſhining like the ſkin of a ſerpent; it is naked to the top, where it has a tuft of leaves, which are divided into many parts. The flower-ſtalk riſes immediately from the root, and is ſeldom more than three inches high; having an oblong ſwelling hood (or ſpathe) at top, which opens lengthwiſe, ſhowing the ſhort thick pointed ſtyle within, upon which the flowers are cloſely ranged.

It grows naturally in ſeveral of the iſlands of America. Mr. Miller received roots of it from Barbuda: [alſo in Surinam, and Japan, where they prepare a medicine from the acrid roots, which they call Konjakſ, and eſteem as a great emmenagogue: diſſolute women uſe it there to procure abortion [4]. In the Society iſles it is cultivated for the ſake of the roots, which are eaten in a ſcarcity of the Bread-fruit, notwithſtanding their extreme acrimony [5].]

2. This has an oblong thick root full of joints, from which ariſe ſeveral leaves, ſhaped like thoſe of the common Arum, but their foot-ſtalks are covered with rough protuberancies. The ſtalk which ſupports the flower is ſhort, and ſet with the like protuberancies, and at the top is a ſpathe, about four inches long, as thick as a man's finger, which opens longitudinally, and expoſes the ſpadix, which is ſet with flowers.

It grows naturally in the iſland of Ceylon, and in ſeveral parts of India.

[3. The flowers appear firſt; after they are arrived to a ſtate of perfection, the leaves come out at a ſmall diſtance, in a conic form, very cloſely rolled together. They are nearly ovate when expanded, and petioled. The plant has no ſtem. The globe of flowers is nearly the colour of the ſpathe, which is beautifully variegated with ſcarlet and yellow. The corolla has four, erect, very thick, narrow, obtruncated petals. The ſtamens have four flattiſh filaments riſing from the receptacle, longer than the corolla. Style rather longer than the

[4] Thunb. jap. & trav. 3. 163. engl. edit. [5] Forſter. obſcul. 80.

ſtamens: ſtigma biſid. Seeds large, roundiſh, ſingle, incloſed within the receptacle.

Native of North America, in ſwamps and borders of meadows: april and may.—The vulgar names of Scunk Cabbage and Scunkweed are taken from its rank ſmell, nearly reſembling that of a Scunk or Polecat.

The roots dried and powdered are an excellent remedy in aſthmatic caſes. It may be given with ſafety, to children, in doſes of four, five or ſix grains, and to adults, in doſes of twenty grains and upwards. It appears to be antiſpaſmodic, and bids fair to be uſeful in many diſorders. In collecting the roots, particular care ought to be taken that the *white hellebore*, or *poke-root*, which ſome call Scunkweed, be not miſtaken for this.—There is an obvious diſtinction, the former has a ſtalk, but this has none [e].

Cattle do not touch it during the ſummer. The Swedes ſettled in North America call it *Byorn-blad*, or *Byoru-retter* (Bear's-leaf or Bear's-root): becauſe the Bears, when they leave their winter habitations in the ſpring, are very fond of it [f].]

4. This has roots like the common Arum, and the leaves come out each on a ſeparate foot-ſtalk, immediately from the root, as in that plant. It has not flowered in England. Siberia is its native country.

5. This has ſlender jointed ſtalks, which put out roots at every joint, that faſten to the trunks of trees, walls, or any ſupport which is near them, and thereby riſe to the height of twenty-five or thirty feet. The leaves are placed alternately, ſtanding upon long foot-ſtalks; they are four or five inches long, and two and a half broad, having ſeveral oblong holes in each, ſo that on the firſt view they appear as if eaten by inſects. The flowers are produced at the top of the ſtalk, which always ſwells to a larger ſize in that part than in any other; theſe are covered with an oblong ſpatha (or hood) of a whitiſh green colour, which opens longitudinally on one ſide, and ſhews the ſpadix cloſely covered with flowers, of a pale yellow, inclining to white. When this plant begins to flower, it ſeldom advances farther in height, ſo that theſe ſeldom are more than ſeven or eight feet high; but the leaves are much larger on theſe, than thoſe of the plants which ramble much farther.

It grows naturally in moſt of the iſlands in the Weſt-Indies, [and in the iſland of Tanna in the South Seas; and was cultivated by Mr. Miller in 1752 [g].

Quebitea of Aublet (guian. t. 327.) is probably to be referred to this genus [h].]

PROPAGATION AND CULTURE.

1, 2. Theſe ſorts being tender, require a warm ſtove to preſerve them in England. The roots muſt be planted in pots filled with light kitchen-garden earth, and plunged into the tan-bed in the ſtove, where they ſhould conſtantly remain; in the winter they muſt be watered very ſparingly, but in warm weather, when the plants are in vigour, they muſt be often refreſhed, but it ſhould not be given them in too great quantities; with this management the plants will flower, but their roots do not increaſe here.

4. This requires a ſhady ſituation, and will bear the greateſt cold of this country.

5. This plant is eaſily propagated by cuttings, which, if planted in pots filled with poor ſandy earth, and plunged into a hot-bed, will ſoon put out roots, if they had none before; but there are few of the joints which have not roots: the plants being tender, will not live in the open air in England, therefore the pots ſhould be placed near the walls of the hot-houſe, againſt which the plants will climb, and faſten their roots into the wall, and thereby ſupport the ſtalks. They ſhould have but little water given them in the winter, but in warm weather it muſt be given them three or four times a week, and in the ſummer the free air ſhould be admitted to them in plenty. The plants have no particular ſeaſon of flowering, for they ſometimes flower in autumn, and at other times in the ſpring, but they do not ripen their ſeeds in England.

Theſe plants are preſerved in the gardens of the curious in England and Holland, more for the ſake of variety than for beauty; for except the fifth ſort, there is not any of them which make much appearance; that indeed may be ſuffered to have a place againſt the wall of the ſtove, over which it will ſpread, and cover the nakedneſs of the wall; and the leaves, which are ſo remarkably perforated, remaining all the year, make a ſingular appearance.

All the other ſorts of Dragon being tender plants, will not live in this country, unleſs they are preſerved in the warmeſt ſtoves; the ſeveral American ſorts grow naturally in the woods in Jamaica, and other hot parts of America; the climbing ſorts twiſt themſelves round the trunks of trees, into which they faſten their roots, which are ſent forth from their joints, and riſe to the height of thirty or forty feet. Theſe climbing ſorts are eaſily propagated by cuttings, which, being very ſucculent, may be brought over to England in a box of dry hay, if they are packed up ſeparate, ſo as not to injure each other by the moiſture, which is apt to flow out at the part where they are cut off, which may occaſion a fermentation, and thereby rot the cuttings. When the cuttings arrive, they ſhould be planted in ſmall pots filled with light freſh earth, and plunged into a hot-bed of tanner's bark, being very careful not to let them have too much moiſture until they have taken root, leſt it rot them: when they have taken root, they muſt be frequently refreſhed with water; and when they are grown pretty large, they ſhould be placed in the bark-bed in the ſtove, where they muſt be placed near ſome ſtrong plants, to which they may faſten themſelves, otherwiſe they will not thrive; for though they will ſend forth roots at their joints, which will faſten to the mortar of the ſtove, when placed againſt the wall, yet they will not thrive near ſo well as againſt a ſtrong plant, which will afford them nouriſhment.

The other ſorts are propagated by off-ſets from their roots; theſe may be procured from the countries of their growth, and ſhould be planted in tubs of earth, about a month before they are put on board the ſhip to tranſport them; theſe tubs ſhould be placed in a ſhady ſituation until they have taken root. In their paſſage great care ſhould be had to keep them from ſalt water, as alſo not to let them have too much water given them; for if they have a little water once or twice a week at moſt, while they are in a hot climate, and when they are come into a cooler climate, once in a fortnight, this will be ſufficient for them; and it ſhould be done ſparingly, leſt it rot them; for if the tops of the plants ſhould decay for want of water in their paſſage, if the roots are not rotted, they will ſoon recover with proper care.

When the plants arrive, they ſhould be tranſplanted into pots filled with light freſh earth, and plunged into a hot-bed of tanner's bark, and gently watered until they have taken good root, after which time they will require to be frequently refreſhed with water; but as their ſtems are very ſucculent, they muſt not have too much moiſture. Theſe plants ſhould be conſtantly kept in the ſtove, where, in hot weather, they ſhould have freſh air admitted to them; but in winter they muſt be kept very warm, otherwiſe they cannot be preſerved in this country.

Theſe plants will riſe to the height of three, four, or five feet, and will afford a very agreeable variety amongſt other tender exotic plants in the ſtove.

Scapes rooted, leaves ovate, flowers umbelled.

DESCRIPTIONS, *&c.*

These are herbs of a ſmall ſize, and ſingular ſtructure. The leaves, in moſt of the ſpecies, only next the root, furniſhed with glandulous hairs on the upper ſurface, and fringed with them round the edge: theſe hairs have each a ſmall globule of a pellucid liquor like dew, continuing even in the hotteſt part of the day, and in the fulleſt expoſure to the ſun. Hence their Engliſh name of *Sun-dew.*

1. This is ſingular for having a ſeſſile flower in the boſom of the root-leaves [1].

2. It reſembles the next ſpecies, but is larger, and has ſeſſile leaves, rounded at the ſummit, but gently attenuated towards the baſe. This and the foregoing are natives of the Cape of Good Hope, where they were firſt obſerved by Thunberg [2].

3. Root perennial, black. Root-leaves many, forming a tuft, two or three lines in length and breadth, ſet with red hairs about the edge, and on the upper ſurface, the under ſurface ſmooth; the petioles red, and half an inch or eight lines in length, ciliate at the baſe. Scape erect, round, ſlender, ſimple, three or four inches in height. Flowers in a kind of racemed ſpike, bent in at the top before flowering time; they point one way, are alternate, erect, and from ſix to eleven in number; the pedunceles are half a line or a line in length. Corolla white: calyx ſmooth: ſtigmas obtuſe, white. Bractes none.—Flowers open from nine to twelve [3]. The young leaves, before they are expanded, are rolled inwards, and at the ſame time bent in to the very peduncle. *Drosera* and *Utricularia* are the only two plants which are common to Sweden and the Eaſt-Indies, and they are both water plants [4]. And Linneus remarks that Drosera is a native of all the four continents [5], on bogs. The Eaſt-Indian plant, however, is probably different from the European, and Vahl has ſeparated it under the name of Drosera Burmanni; with radicate ſcapes and ſmooth calyxes, the leaves ſpatulate and ſeſſile. He

[1] Linn. ſuppl. [2] Ibid. [3] Pollich & Krocker. [4] Ibid & Linn. ſuec. [5] Linn. zeyl.

adds, that the leaves are attenuated at the base, a quarter of an inch in length, and that the cilias are slender and equal. It is distinct from the preceding species (D. cuneifolia) in the smoothness of the scape and pedicels, and in being only one third of the size[1]. If this be a genuine species, the synonyms of the Flora Zeylanica, Burmann and Loureiro must be applied to it.

With us D. rotundifolia flowers in july and august: and is found on Hampstead heath; at Battle's well near Harefield, and Iver heath; on Hinton and Teversham moors and Gamlingay bogs in Cambridgeshire: on Malvern chace—Birmingham heath—Selborne in Hampshire—Ludgvan Lee, on the Barton and Moors; and Senan, in Torvorian Commons; Cornwall.—Halston in Northamptonshire.—Near Mansfield and Oxton in Nottinghamshire. In Scotland frequent.

β. Observed in Devonshire by Tho. Willisel.

The whole plant is acrid and sufficiently caustic to erode the skin; some ladies, however, know how to mix the juice with milk, so as to make it an innocent and safe application to remove freckles and sun-burn. The juice that exudes from it unmixed will destroy warts and corns.—The plant has the same effect upon milk as the *Pinguicula vulgaris*; and like that, too, is supposed to occasion the rot in sheep. Is not the sour coagulated milk of the Syrians, called *Leban* or *Leven*, at first prepared with some plant of this kind[2]?

It is called in English *Sun-dew*, *Youth-wort*; in the north parts *Red-rot*, and in Yorkshire *Moorgrasse*[3]; in German, *Sonnenthau*, *Sindau*, *Lefflenkraut*; in Dutch, *Zonnedauw*, or *Loopjekruid*; in Danish, *Soelding* or *Himmeldug*; in Swedish, *Marie-Silesblar*; in Smoland, *Daggort*; in Italian, *Rugiada del Sole*; in Spanish, *Rociada*, or *rocio del sol*; in Portugueze, *Rossolina*; in Russian, *Solnenaja trawa*.

4. Linneus is of opinion that this is scarcely specifically distinct from the foregoing, since they agree in every thing except the form of the leaves. Pollich affirms that the former has no bractes. Lyon (M. S. in Relh. cant.) writes that the latter has very small, sharp bractes, the length of the pedunicles.—According to Hudson they have both six styles, and three-valved capsules. Gærtner informs us that the capsule opens to the middle into three, four or five valves. Scopoli does not hesitate to join this and the round-leaved Sun-dew together, and affirms that he has many specimens showing a gradual change from the one to the other. Haller will not allow that they ever change one to the other.—This seems not to be so common as the round-leaved sort: Mr. Woodward, however, informs us that it is frequent in Norfolk: and Mr. Lightfoot, that it is so also in Scotland. On Brigstear moss near Kendal, it grows to twice or thrice the size it does about London.—It is also found on Hinton moor near Cambridge: on Bagshot heath in Surrey; and at Selborne in Hants.

β. Great Sun-dew, which Mr. Hudson makes a distinct species, because it is larger, has eight styles, and four-valved capsules: is common, as he informs us, in the northern counties; also in Devonshire, Hampshire and Norfolk; three miles from Carlisle towards Scotland; where Mr. Dickson found it near Fort Augustus. Near Ellesmere in Shropshire, and in Ireland.

γ. Found by Tho. Willisel in Yorkshire between Doncaster and Bautrey: and by Mr. J. Sherard on Westfield down near Hastings.

These plants have the same property with *Dionæa Muscipula*, of entrapping small insects within their folded leaves. It was discovered by Mr. Whately, a surgeon, in august 1780. On inspecting some of the contracted leaves, he observed a fly in close imprisonment; and on centrically pressing other leaves, yet in their expanded form, with a pin, he observed a sudden elastic spring of them, so as to become inverted upwards, and as if were encircling the pin. The same account occurs in a German author (Wroth. beytrog. p. 64.) in july 1779. An ant was placed on the middle of a leaf: the insect endeavoured to escape, but was held fast by the clammy juice at the points of the hairs: in some minutes the short hairs on the disk of the leaf began to bend, then the long hairs, and laid themselves upon the ant: after a while the leaf began to bend, and in some hours the end of the leaf was so bent inwards as to touch the base. The ant died in fifteen minutes[4].

5. Root putting out spiral threads. Leaves scabrous, with tubercles underneath. Flowers violet-coloured. Native of the Cape of Good Hope[5].

6. The stem has a few leaves on it, and from two to four pedunceled flowers at the end. Capsule twice as long as the calyx. The whole plant has bristles glandular at the tip[6]. Ray will not allow it to be a species of this genus. Allstroemer observed that it had constantly ten stamens; and therefore it would be an *Oxalis*, if the flowers were in an umbel, and the peculiar property of the leaves, together with its one-celled capsule, did not detain it in this genus.—Native of Portugal[7]. Collected there by Tournefort.

7. Stems a foot high, pubescent. Leaves alternate, with glutinous hairs. Flowers terminating, one to three, large, on peduncles[8]. The bottom of the corolla dark. Stamens black, the length of the calyx: anthers yellow, cordate. Pistil black: germ ovate, and round the top, but not on the top of it, five black styles, the length of the corolla, stigmas several times dichotomous, even into hairs[9]. Native of the Cape of Good Hope.

8. Stem herbaceous, a little branched. Leaves alternate, petioled. Peduncles axiliary, with two or three flowers[10]. Native of the East-Indies.

The Ceyloneſe call it *Kandulaeſſa*, from *Kandulu*, a tear: the leaves being surrounded by drops, as in our European species. The stem is half a foot high, and very slender. The leaves are extremely fine, and come out alternately all over the stem and branches, and are bent upwards at the ends. The peduncles are the length of the leaves, or longer, and sustain three flowers or more; but the weaker only one[11].

9. Stem none. Leaves *next the ground only* on long petioles. Scapes various, naked, five inches long, terminated by an umbellule of about five flowers, with corollas of five petals. Native of China[12].

PROPAGATION AND CULTURE.

These plants are not easily preserved in gardens. They must be taken from their native bogs, with a sufficient quantity of bog-earth and water moss, and planted in pots, set in pans constantly supplied with water. They will succeed better if defended from the sun, and well enveloped in moss kept constantly wet.

DRYANDRA. (*So named by Thunberg in honour of his most beloved friend Jonas Dryander, M. A. a Swede, and most excellent botanist*[13]. *New Librarian to Sir Joseph Banks, and the Royal and Linnean Societies.*)

Thunb. gen. nov. 60. *Fl. jap.* 13. *Juss.* 389. *Lin. gen. ed. Schreb.* n. 1564.

Class. 16. 4. Dioecia Monadelphia.

Nat. order of *Tricoccæ*.—*Euphorbiæ*. Juss.

GENERIC CHARACTER.

* *Male.*

CAL. *Perianth* two-leaved; *divisions* ovate, acute, shorter than the corolla.

COR. five-petalled. *Petals* obovate-oblong, from reflex patulous, unguiculate.

STAM. *Filaments* nine, united below into one body, unequal, shorter by half than the corolla. *Anthers* minute.

* *Female.*

[1] Symb. 3. 50. [2] Withering. [3] Gerarde.

Per. tricoccous or tetracoccous, three-grooved or four-grooved, wrinkled, fleshy.
Seeds solitary, oblong.
Obs. *What Thunberg calls the corolla, Jussieu names the calyx.*

ESSENTIAL CHARACTER.

Cal. two-leaved. *Cor.* five-petalled.—Or, *Cal.* five-leaved, resembling a corolla, surrounded by a two or three-leaved calycle. *Stam.* nine. *Fruit* three or four-grained.

SPECIES.

1. Dryandra cordata.
Lin. syst. 612. *Thunb. jap.* 267. *t.* 27. *Kæmpf. amœn.* 5. 789. *ic. select. t.* 23.
D. oleifera. *Lamarck encycl.* 2. 329.

DESCRIPTION, *&c.*

Stem arboreous, a fathom or more in height. Branches round, with a wrinkled back, dotted, smooth. Leaves at the ends of the twigs, approximate, alternate, petioled, cordate, acute, entire, five-nerved, the nerves branching, smooth, paler underneath, spreading, a hand in length and breadth. Petioles almost the length of the leaf, round. Flowers terminating, in a panicle, the branches of which are dichotomous or trichotomous, and patulous. Petals yellow. From the seeds they express an oil for lamps, and the table [a].

Stipules caducous; the end of the petiole glandulous. Peduncles among the leaves terminating, three or four-flowered.—*Elæocarpa* of Commerson, commonly called *Arbre à huile* or Oil-tree, if not the same with this, is of this genus. It has usually ten stamens, the outer shorter, and five oily seeds [b].

Since Lamarck, from Commerson's specimens, describes the peduncles on the female tree as simple and one-flowered, which in Kæmpfer's figure are compound, we are not certain that the tree cultivated in the royal garden in the island of Mauritius is of the same species with that which Thunberg observed in Japan [c]: where it is called *Abirasin.*]

DRYAS. (*So called by Linnæus, from the Dryades or Nymphs of the oaks; the leaves bearing some resemblance to those of the oak.*)

DESCRIPTIONS, *&c.*

1. This is a very small plant, native of Siberia; the radical leaves are commonly ternate, compound, consisting of a middle leaflet longer than the rest, and two lateral ones: all the leaflets are deeply cut or divided, but vary much in different individual plants as to breadth and length; sometimes the leaves have more than three divisions; they are of a bright green, and very smooth; the foot-stalk is round: the stalk is terminated by a single flower, which is large in proportion: the calyx is outwardly green, and inwardly lanuginous, and of a silvery appearance: the corolla is pale yellow, the petals striated: the stamens are extremely numerous, and short; the germs converge into a globe, and are coated with a white down.

2. This delicate ever-green plant, with its snow-white blossoms, is a great ornament to alpine heights [a]. The stalk and branches are woody and perennial, lying flat upon the ground, and spreading wide about the root in tufts [b]. Leaves ever-green, ovate, turned back at the edge, ending very obtusely, and sometimes emarginate, deeply and bluntly serrate, or more properly crenate, hard and stiff, of a dark green, wrinkled surface on the upper side, and hoary* underneath, having woolly foot-stalks, and a large halbert-shaped stipule to each, embracing the stem. Peduncles naked, downy, scattered with purple hairy glands, each bearing one flower [c], an inch in diameter [d]; consisting generally of eight petals, but sometimes of ten or six, seldom of five [e]. Seeds oblong, gibbous on one side, straightish on the other, somewhat villose, reddish brown, narrowing at bottom, ending at top in a feathered flexile tail, eight times the length of the seed [f]. The corolla is frequently double. The structure of the stipules renders this genus the connecting link between *Rosa* and the rest of the *Senticosæ* [g].

Monf. Villars says, it has the leaves of Germander, the petals and fruit of Anemone, the calyx and stamens of Geum, with which genus it might be united. It forms large tufts like *Arbutus alpina*, but the leaves are crenate and smaller, and the flowers are very different.

Native of high mountains in Lapland, Denmark, Switzerland, where Ray observed it on Thuiri, one of the highest points of mount Jura; the Grisons, Savoy, Austria, Carniola, Stiria, Carinthia, Germany, France, Italy, Siberia, Ireland, Scotland, and the north of England. As between Gort and Galloway, where it was found by Mr. Heaton, and near Sligo in Ireland. Breadalbane, Isle of Skye; Rossshire; Sutherland, and Argyleshire, in Scotland. Arncliff Clowder in Littendale, near Kilnsay; and near Settle, in Yorkshire. It flowers in June. No cattle eat it [h].

DESCRIPTION, *&c.*

The firſt ſtems are procumbent, four-cornered, brachiate; the laſt dichotomous and flower-bearing. Freſh green branches puſh forth in the ſpring from the dry ones of the former year, the extreme ones are dichotomous, and bear flowers. Leaves ſubulate, ſomewhat three-cornered, mucronate; thoſe at the ſubdiviſions of the ſtem are lanceolate, with three teeth on each ſide. Peduncles ſhorter than the flower. Calyx erect: corolla crowned, as in *Silene*, purple or white; petals very narrow, ſpreading: ſtamens erect. Biennial[1].—Native of Barbary, Italy, Iſtria.

This plant in its adult ſtate becomes ſhrubby. Branches very frequent, patulous. Upper leaves flat, convex underneath, under the topmoſt branches below the middle on both ſides putting forth ſpiny teeth on the edge. Petals red. Capſule ſo covered with the converging hardened calyx, that they ſhould fall together, without the capſules opening: it is not therefore five-valved, as Micheli aſſerts it to be; nor is it *circumciſſa*, as Linnæus[a].

The fruit is thus deſcribed by the accurate Gærtner. It is a capſule covered by the calyx, ovate, mucronate at top, ſlightly narrowed at bottom, membranaceous, very thin, diaphanous, one-celled, clipped round above the middle. The ſeed is faſtened by a filiform umbilical chord, aſcending from the bottom of the capſule to the emarginate ſide of the ſeed: it is ſingle, the ſame ſize with the capſule, kidney-form, beaked, keeled on the back with a prominent line, compreſſed, lens-ſhaped, ſmooth, ſomewhat ſhining, ſulvous, or bay yellow.

Introduced 1775, by Joſ. Nich. de Jacquin[b]. It is named *Sperage Thiſtle* by Johnſon in Gerarde. In Italy they call it *Erba Ciaccia*, or Aſs herb, becauſe that animal feeds freely on it.

Leaves elliptic, quite entire.

DESCRIPTIONS, *&c.*

Theſe are ſhrubs with quadrangular branches. The flowers are in looſe ſpikes either from the axils, or at the ends of the branches. They have generally axillary ſpines; and they are ſo alike in their manner of flowering, as well as in the ſtructure and colour of the flower, that it is doubtful whether they may not be all one ſpecies[a].

1. This grows fifteen feet high, with alternate branches, erect or reclining. Spines awl-ſhaped, oppoſite, but very frequently wanting. Leaves lanceolate, on ſhort petioles, acute, bluntly and unequally ſerrate above the middle, ſmooth, oppoſite, two inches long. Racemes looſe, wide, reclining, both axillary and terminating. Flowers ſlightly ſweet-ſmelling, very many, blue, on very ſhort peduncles. Fruit yellow; the calyx alſo then becoming yellow, and like a berry, the whole being changed, and different from its former ſhape[b].

Gærtner thus deſcribes the fruit. It is a ſucculent Berry, involved in the calyx, ovate-globular, red or ſaffron-coloured, one-celled, with four hard, three-ſided ſtones, bowed on the back, and two-celled. Calyx when ripe bellying, marked with four deeper-coloured fillets, and four others that are pale and diaphanous; it is contracted above, and five-toothed; with awl-ſhaped teeth twiſted towards

[a] Juſſieu & Linn. ſuppl. [b] Jacquin.

the right hand. There is a single seed in each cell, of the same shape with it, reflexent, fixed by its base.

Linnæus originally made two species of this, and Miller continues them distinct; adding a third, under the name of *Duranta erecta*, which is probably our second species D. Ellisia. He thus describes them.] 1. Has many trailing branches, armed with hooked thorns at every joint, and having oblong leaves, placed without order, and slightly serrate. Flowers from the side of the stalks in pretty long bunches, like those of the common Currant; they are of a pale blueish colour, and are succeeded by brown berries, not unlike those of the Hawthorn; having one cell, and including four angular seeds. 2. (*β inermis.*) Has a branching woody stalk, seven or eight feet high. Leaves ovate-lanceolate, three inches long, and an inch and half broad in the middle, serrate, of a lucid green colour, and opposite. Flowers in long, terminating bunches; they are blue, and are succeeded by pretty large, round, yellow berries, containing four angular seeds. 3. Rises with a strong, upright, woody stem, to the height of ten or twelve feet, covered with a white bark, dividing into many branches, armed with sharp thorns. Leaves ovate, stiff, an inch long, and three quarters of an inch broad, quite entire. Flowers in long terminating bunches; they are blue, and are succeeded by small round yellow berries, containing four angular seeds.

[Native of South America, and the West-India islands.

Introduced before 1733 by William Houstoun, M. D. [a]

2. This shrub is a fathom in height or more, branched and even. Branches long, reclining, quadrangular, subdivided, with axillary, opposite, awl-shaped spines, which however are sometimes wanting. Leaves petioled, opposite, ovate-lanceolate, acuminate, serrate, nerved, smooth on both sides. Racemes compound, terminating, brachiate, many-flowered. Flowers on short peduncles, and blue.

The specific character of this and the preceding, taken from the contortion of the calyx above the fruit, is vague and insufficient; since the differences occur frequently in the same raceme. They are therefore in all probability not specifically distinct [b]. Jacquin also remarks, that it is extremely like the first species, except that the fruiting calyx is not twisted in the upper part, but continues convergent and erect.

Notwithstanding this approximation, Dr. Patrick Browne made it a distinct genus under the name *Ellisia*, from Mr. Ellis the ingenious author of a treatise on Zoophytes, or plant-like marine productions of an animal nature. He says that this shrub rises frequently to the height of six or seven feet; that the leaves are very like those of green Tea; and that the branches, though sometimes beset with thorns, are often otherwise.—Native of the West-Indies. In Jamaica frequent in hedges, between Kingston and San Jago de la Vega.

Cultivated in 1739, by Mr. Miller.

3. This differs no otherwise from the two other species than in the leaves. Native of South America, and found there by Mutis [c].]

PROPAGATION AND CULTURE.

These plants being natives of warm countries, they require a stove to preserve them in England; they are propagated by seeds, which should be sown in small pots, and plunged into a hot-bed of tanner's bark; and when the plants are fit to remove, they must be planted each into a separate small pot filled with light earth, and plunged into the hot-bed again, observing to shade them till they have taken new root, then they must be treated in the same manner as other plants from the same country.

The second sort (*β*) may be propagated by cuttings, which may be planted in any of the summer months; but these should be plunged into a moderate hot-bed, and shaded from the sun till they have taken root, then they may be treated in the same manner as the seedling plants. This being not so tender as the other two, may be placed in the open air in summer; and if kept in a moderate temperature of warmth in the winter, will thrive better than in great heat. I kept some of the plants of this sort three winters, in a dry warm glass case without fires, and they succeeded pretty well; but the winter of 1763 proving severe, their leaves fell; they put out again, however, very well.

[These, whether they be species or varieties, may also certainly be increased by cuttings, which put out roots very readily.] They thrive best during winter in a temperate heat; for when they are too tenderly treated, their shoots are apt to be weak, and then they are attacked by vermin. In summer, place them in a warm sheltered situation in the open air [a].

SPECIES.

1. Durio Zibethinus.

Lin. syst. 698. *Reich.* 3. 587. *Rumph. amb.* 1. 99. *t.* 29.

DESCRIPTION, *&c.*

A lofty tree with flowers below the leaves, which are alternate. Native of the East-Indies [a].

The leaves resemble those of the cherry, but are not dented at the edges, and are therefore in reality more like nutmeg leaves. The flowers are borne in loose heads. They are large, and of a pale yellow-white colour. The fruit is the size of a man's head, and round or oblong; resembling in some degree a rolled-up hedge-hog, with a hard bark or rind; the fleshy part of the fruit is of a creamy substance, and of a delicate taste; but of an unpleasant heavy smell, somewhat resembling that of rotten onions; and the smell of the breath of those who eat it is infected also in a high degree; but when once a person has accustomed himself to eat this fruit, he generally considers it as the most excellent of all others [b].

SPECIES.

1. Duroia Eriopila.

Lin. ſyſt. 342. *ſuppl.* 209. *Meriau. ſurin. t.* 43?

DESCRIPTION, *&c.*

A tree with thick, unequal branches, hirſute at the end. Leaves terminating, oppoſite, approximating, many, ſubpetioled, a ſpan in length, obovate, quite entire, obtuſiſh, ribbed, pubeſcent above, nacted underneath. Petioles very ſhort, hirſute. Flowers at the ends of the branches, ſeſſile, heaped, many, ſeveral of them abortive. Corollas white, like thoſe of *Nyctanthes Sambac*. Fruit ſomewhat larger than a turkey's egg, ſpherical, covered very thick with erect, brown hairs; umbilicate, with the hollow calyx. It is well flavoured, and much eſteemed at Surinam, of which it is a native*.

DWALE. See *Atropa*.]

DWARF-TREES. Theſe were formerly in much greater requeſt than they are at preſent; for though they have many advantages to recommend them, yet the diſadvantages attending them greatly overbalance; and ſince the introducing of eſpaliers into the Engliſh gardens, Dwarf-trees have been in little eſteem for the following reaſons:

1ſt, The figure of a Dwarf-tree is very often ſo much ſtudied, that, in order to render the ſhape beautiful, little care is taken to procure fruit, which is the principal deſign in planting theſe trees.

2dly, The branches being ſpread horizontally near the ſurface of the ground, render it very difficult to dig or clean the ground under them.

3dly, Their taking up too much room in a garden, eſpecially when they are grown to a conſiderable ſize, ſo that nothing can be ſown or planted between them.

4thly, Theſe trees ſpreading their branches near the ground, continually ſhade the ſurface of the earth; ſo that neither the ſun nor air can paſs freely round their roots and ſtems, to diſſipate noxious vapours, whereby the circumambient air will be continually replete with crude rancid vapours, which, being drawn in by the fruit and leaves, will render its juices crude and unwholeſome, as well as ill taſted.

It is alſo very difficult to get to the middle of theſe Dwarf-trees in the ſummer, when their leaves and fruit are on the branches, without beating off ſome of the fruit, and breaking the young ſhoots; whereas, the trees on an eſpalier can at all times be come at on each ſide, to tie up the new ſhoots, or to diſplace all vigorous ones, which, if left on, would rob the trees of their nouriſhment.

Add to this, the fruit-buds of all ſorts of Pears and Apples, and moſt ſorts of Plumbs and Cherries, are firſt produced at the end of the former year's ſhoot, which muſt be ſhortened in order to keep the Dwarfs to their proper figure, ſo that the fruit-buds are cut off, and a greater number of branches are obtained, than can be permitted to ſtand; ſo that all thoſe ſorts of fruit-trees, whoſe branches require to be trained at their full length, are very improper to train up as Dwarfs; and the Peaches and Nectarines which will bear amputation, are too tender to be trained ſo in this country.

Theſe evils being entirely remedied by training the trees to an eſpalier, has juſtly gained them the preference; however, if any one has a mind to have Dwarf-trees, notwithſtanding what has been ſaid, I ſhall lay down a few rules for their management.

If you deſign to have Dwarf Pear-trees, you ſhould bud or graft them on Quince ſtocks; but as many ſorts of Pears will not thrive if they are immediately budded or grafted on Quince ſtocks, ſo ſome of thoſe ſorts which will take freely, ſhould be firſt budded on the Quince ſtocks; and when theſe have ſhot, the ſorts you intend to cultivate, ſhould be budded into theſe; for free ſtocks are apt to make them ſhoot ſo vigorouſly, as not to be kept within bounds. Theſe graſts or buds ſhould be put in about four or ſix inches above the ſurface of the ground, that the heads of the trees may not be advanced too high; and when the bud or graft has put out four ſhoots, you ſhould ſtop the end of the ſhoots, to force out lateral branches.

Two years after budding, theſe trees will be fit to tranſplant where they are to remain; for though many people chuſe to plant trees of a greater age, yet they ſeldom ſucceed ſo well as young ones. The diſtance theſe trees ſhould be planted is twenty-five or thirty feet aſunder, for leſs will not do if the trees thrive well. The ground between them may be cultivated for kitchen-garden herbs while the trees are young, but you ſhould not ſow or plant too near their roots.

In order to train your trees regularly, you ſhould drive ſtakes into the ground round the tree, to which the branches ſhould be faſtened down with liſt in a horizontal poſition; for if they are ſuffered to grow perpendicularly while young, they cannot be afterwards reduced without great violence to any tolerable figure. The neceſſary directions to be afterwards followed are, not to ſuffer any branches to croſs each other; and always in ſhortening any ſhoots be ſure to leave the uppermoſt eye outwards, whereby the hollowneſs in the middle of the tree will be better preſerved; and be careful to rub off all perpendicular ſhoots in the middle of the trees, as ſoon as they are produced. The other neceſſary rules you will find under the article of PRUNING.

The ſorts of Pears which do beſt in Dwarfs, are all ſummer and autumn fruits; for winter Pears are not worth planting in Dwarfs, they ſeldom bearing well, nor are ever well taſted, and commonly are very ſtony, becauſe they are commonly grafted on Quince ſtocks.

Apples are alſo planted in Dwarfs, moſt of which are now budded or grafted on Paradiſe ſtocks; but as theſe are for the moſt part of a ſhort duration, they are not profitable, and are fit only for ſmall gardens as a matter of curioſity, producing fruit ſooner, and in greater plenty, than when they are upon Crab or Apple ſtocks.

The diſtance theſe trees ſhould be planted, if on Paradiſe ſtocks, ſhould be ſix or eight feet, and upon Dutch ſtocks eighteen or twenty; but if on Crab ſtocks, twenty-five or thirty feet aſunder each way. The management of theſe being the ſame with Pears, I need not repeat it.

Some perſons alſo plant Apricots and Plumbs for Dwarfs, but theſe ſeldom ſucceed well, as being of a tender conſtitution; and thoſe which will produce fruit on Dwarfs, are much more likely to do ſo when trained on an eſpalier, where they can be much better managed; and therefore I judge it much the better method, as being more certain, and the trees will make a better appearance.

Leaves pinnate, with four pairs of leaflets, spikes axillary, on very long peduncles.
DESCRIPTIONS, *&c.*
1. This rises with a shrubby stalk three or four feet high, with several side branches. Leaves at each joint, hoary, composed of five narrow lanceolate leaflets, which join at their tails to the foot-stalk, and spread out like the fingers of a hand. The branches are terminated by thick spikes of large purple flowers: the spikes are from two to three inches long, and make a fine appearance. It flowers in june and july, and in very warm seasons will sometimes perfect seeds in England. It grows naturally in Crete, and some islands of the Archipelago.
[Lamarck and Jussieu refer this plant to the genus Anthyllis. Linnæus observes that the bracteæ are ovate, acute and scariose. Calyxes sessile, with setaceous villose teeth, the length of the flowers*. It was cultivated in 1748 by Mr. Miller*.]
2. Biennial. Native of Barbary and the Levant. Introduced in 1786, by Monf. Thouin. It flowers in july*.]
PROPAGATION AND CULTURE.
These are propagated by seeds, which should be sown in the autumn, for those which are sown in the spring often fail; they must be sown in pots, and placed under a frame in the winter, where they may be protected from frost. In the spring the plants will come up, they should be kept clean from weeds, and refreshed now and then with water. When these have acquired strength enough to be removed, they should be each planted in a separate small pot filled with light earth, and plunged into a moderate hot-bed just to promote their taking new root; then they should be gradually inured to bear the open air, into which they should be removed the latter end of may, placing them in a sheltered situation, where they may remain till autumn, when they must be removed into shelter; for these plants will not live in the open air through the winter, nor should they be too tenderly treated, lest they draw up weak. I have found them succeed best when placed in an airy glass case without fire in winter, where they will have more sun and air than in a green-house. During the winter season, the plants must be sparingly watered, but in the summer they will require to be often refreshed. The other management is the same as for other of the hardier exotic plants, among which they will make a fine variety.

Leaflets gashed, unarmed.
DESCRIPTIONS, *&c.*
1. Root perennial, creeping. Stalks branching, five or six inches high, with short thick leaves, terminating in two or three sharp thorns, and opposite, in pairs. Flowers in an umbel, on a naked peduncle, which arises from the side of the stalk. Under the umbel an involucre composed of several leaves, terminating in sharp spines. Corolla white. It flowers in june.
Native of the sea coast of Europe, especially in the Mediterranean sea.
[It was found by Mr. Ray on the sea coast of Lancashire, and by Mr. Blackstone between Feversham and Sea Salter. In the former in these places it has lately been searched for without success*.]
2. Root perennial. Stalk near a foot and half high; whence come out two opposite side branches at every joint. At the lower part of it are leaves finely divided, like those of the Carrot. The flowers

* Mant. Hort. kew. † Ibid.
* Withering.

grow

grow in ſmall umbels at the extremities of the branches, having a ſhort prickly involucre. It flowers in july. [Native of the ſea-coaſt of Apulia. They were both cultivated by Mr. Miller before 1759.]

PROPAGATION AND CULTURE.

Theſe plants not producing ſeeds here, are increaſed by their creeping roots. Tranſplant them the beginning of march, a little before they ſhoot. Place them in a warm ſituation, and a dry ſoil: or elſe cover them in winter to prevent the froſt from deſtroying them.

Stem one-headed, leaves ſpiny, all pinnatifid and waſhed, root creeping.

DESCRIPTIONS, &c.

[Theſe are herbaceous plants, ſome of them large and lofty. The leaves are alternate, thorny and pinnatifid. The heads of flowers are uſually ſolitary at the end of the ſtem and branches.]

1. Root perennial. Stalks many, four or five feet high. Leaves long and jagged, divided into many ſegments almoſt to the midrib, the jags ending in ſpines; they are of a dark green on their upper ſide, but woolly on their under. There are ſeveral globular heads of flowers on each ſtalk. The florets are commonly blue, but ſometimes white. Theſe come out in july, and the ſeeds ripen in auguſt.

[Linnæus obſerves, that the ſtem is branched, many-flowered, pubeſcent, with ſpreading villoſe hairs. Leaves hairy on the upper ſurface. All the ſcales of the calyx pubeſcent to the very tip[1].—Uſually quite ſmooth, according to Gouan. In its wild ſtate it is only a cubit and half in height; in the garden it is much higher, leſs hoary, but more hirſute. The outer calyxes are probably barren[2]. The common receptacle is ſpherical, papillofe or warted, and naked; proper none except the bottom of the calyx. Seed acuminate at the baſe, having ſmall whitiſh briſtles ſcattered over it, and preſſed cloſe to it, of a brown bay colour. It has no crown, but a little membranaceous crenulate cup, probably the remains of the fallen corolla[3].

Native of France, Spain, Italy, the Valais, Auſtria, Carniola, Germany.

Cultivated in 1596, by Gerarde[4].

2. This is of the ſame ſtature with the foregoing, but the ſtem and leaves are more tender. Stem (in the green-houſe) becoming ſomewhat ſhrubby, without glandular hairs. The heads are like thoſe of the firſt ſpecies, but the florets are white, and larger, with the jags reflex-hooked. Among the florets every where come out ſpines formed of unexpanded calyxes, four times the length of the florets, which at length are cloven in two. Native of Egypt and Arabia. Perennial[5].]

3. This has a perennial creeping root, ſending up ſeveral ſtrong ſtalks two feet high, and branching. Leaves cut into many fine ſegments to the midrib. Each branch is terminated by a globular head of flowers, ſmaller than thoſe of the firſt, and of a deeper blue, but ſometimes white: they come out in july.

[Linnæus obſerves, that the ſtem is white-tomentoſe. Leaves ſmooth above, white-tomentoſe underneath. Scales of the calyx ciliate to the very tip[1]. Stem, according to Gouan, a foot in height. All the leaves pinnatifid, pinnules narrow, gaſhed, the ends only of the ſegments prickly: on the ſtem and branches leſs gaſhed, ovate, thorny. This plant is annual, has the appearance of *Carlina* and *Carthamus*, with corymbed branches like them, very tomentoſe. The inner calyxes ſeem to be barren[2]. The roots of this and the firſt ſort are bitter, diuretic and nouriſhing: quadrupeds, eſpecially the horſe and goat, eat the heads.

Native of the South of France, Italy and Siberia. Cultivated in 1629[3].

4. This is an annual plant, with a ſtiff white ſtalk two feet high. Leaves diviſied, ending in

[1] Spec. [2] Illuſtr. [3] Gærtner. [4] Hort. kew. [5] Linn. mant.
[1] Spec. [2] Illuſtr. [3] Hort. kew. from Park. par.

many

many points, which have ſpines; their upper ſide green, covered with brown hairs, their under ſide white and woolly: the ſtalk is terminated by one large head of pale blue flowers, appearing in july.

[Leaves pinnatifid, broadiſh, the jags lanceolate, ending in a very ſmall ſpine; the ſides unarmed, ſtrigoſe on the upper ſurface, with ſtiff hairs, underneath tomentoſe. Calyxes with keeled ſcales, above even, ciliate at the baſe, not collected into a globular head, but in bundles: the lateral or lower calyxes ſmaller, barren, or without any floret [i].

Native of Spain and Portugal. Cultivated in 1731, by Mr. Miller [k].]

5. Root perennial, creeping. Stalks about a foot high. Leaves ſhorter and much finer divided than the preceding ſorts; they are hoary, and armed on every ſide with ſharp thorns: the ſtalks are terminated by one middle-ſized globular head of flowers, blue or white, appearing at the end of june.

Native of Greece, whence Tournefort ſent the ſeeds to the royal garden at Paris.

[This is probably no more than a variety of the third ſpecies.]

PROPAGATION AND CULTURE.

Theſe plants are eaſily propagated by ſeeds, which, if permitted to ſcatter, the plants will come up in plenty, and a few of them may be tranſplanted to the places where they are deſigned to remain to flower; they require no other culture but to keep them clean from weeds: the ſecond year they will flower and produce ſeeds, and the roots will continue two or three years after; but if the ſeeds ſcatter, the plants will become troubleſome weeds; to prevent which, the heads ſhould be cut off as ſoon as the ſeeds are ripe. They will grow almoſt in any ſoil or ſituation.

4. The ſeeds of this ſhould be ſown in the ſpring on a border of light earth, where the plants are to remain.

5. This is eaſily propagated by its creeping roots, or from ſeeds; it loves a dry ſoil and a warm ſituation.

Peduncles axillary, many-flowered, jointed, segments of the corolla waved, leaves elliptic, stem twining.

22. Echites floribunda.
Swartz. prodr. 52.
Racemes corymbed, leaves ovate, acuminate, nerves parallel, branches almost erect.

DESCRIPTIONS, &c.

These plants have something singular in their habit which proclaims them at first sight. The leaves are opposite, petioled, quite entire, veined and shining: the third only has them frequently rugged. Common peduncles seldom longer than the leaves, lateral and alternate, except in *E. spicata*. Flowers void of scent. The nectareous glands, and the downy seeds in follicles, are of great importance in determining the character; whilst the corolla, varying much in the different species, is of no consequence in this respect. The stigma, in all, is glued to the inside wall of the cone formed by the anthers, and which separates at the explosion of the pollen, whilst the outer wall of the cone continues undissolved; the fecundation in the greater part being accomplished within the closed tube of the corolla, but in the rest within the cone stretched beyond the tube.

1. A branched shrub, full of a milky juice, supporting itself by stems partly erect, partly twining upon trees, and mounting them to the height of twenty feet; hence frequently acquiring the air of a tree. Leaves oblong, growing narrower to the base, obtuse at the end, with a small point three inches long. Peduncles sometimes, but rarely, three-flowered. Flowers handsome, very white, with a yellow throat. Native of most of the Caribbee islands, in salt marshes.

2. Stems twining, shrubby, somewhat scabrous. Leaves three inches long. Racemes simple. Flowers about sixteen, green, with a yellowish border, the edge of the tube white, and in form of a pentagon. This is not milky. Native of Carthagena in South America. It flowers in october.

3. A shrub, differing much from its congeners, abounding in milky juice, among other shrubs growing to the height of ten feet, but in savannahs only three feet, and sometimes scarcely a foot high. Stems scarcely twining, climbing. Leaves approaching more or less to an ovate form, either smooth on both sides, or scabrous at the back. The peduncles support a few large, handsome, yellow flowers, hirsute on the outside, and in the tube. The follicles are slender and brown [a].

This rises three or four feet high, with woody stalks, sending out a few lateral branches. Leaves smooth, opposite, of a shining green on their upper sides, but pale and veined underneath. The flowers are produced from the sides of the branches upon long peduncles, at the end of which are commonly four or five buds, but seldom more than one comes to flower; the others withering soon. The flowers being large, and of a bright yellow, make a fine appearance.

It grows naturally in Jamaica in the Savannas, whence it is chiefly known in that island by the name of Savanna-flower.

It is also very common in the island of St. Domingo; flowering from september to march [b]. Dr. Browne says, that all the parts of this plant are extremely poisonous. Cultivated in 1759, by Mr. Miller [c].

4. Stems twining, shrubby. Leaves four inches long. Common peduncles the length of the leaves, often difform, sometimes bifid. Flowers small, white [d]. When the follicles are separated, which is easily done, a drop of watery glutinous liquor, such as the whole plant abounds with, flows out at the two points by which they had cohered. On the mountains near Cape Francois, in Domingo; flowering in december [e].

3. This is a weakly plant, which commonly sustains itself by the help of the neighbouring bushes; and frequently rises to a considerable height among them. The branches and follicles are extremely slender and delicate [f]. Stems twining, round, shrubby. Leaves two inches long. The common peduncles support about six small, yellow flowers. The whole plant abounds in a milky gluten [g].— Frequent about the foot of the mountains in Liguanea, in the island of Jamaica [h]. Flowering in march [i].

Swartz says, that Browne's figure is better than that of Jacquin.

Introduced in 1778, by Wm. Wright; M. D. [k].

6. This climbs to the height of fifteen feet by means of its shrubby, twining, pliant stems, which are woody and suberous at bottom, but round, green and glossy above. The whole abounds in a clear glutinous juice. Leaves roundish-ovate, subcordate at the base, three or four inches long. The common peduncle has from four to seven flowers at the end, in a kind of umbel, with some stipules serving the purpose of an involucre. Flowers large, handsome, the border white, the tube green on the outside [l]. Browne describes them to be pale yellow, with a pretty long slender tube. He remarks, that like the rest of this natural class, it is somewhat of a deleterious nature; and that there is a small variation of it in the drier parts of the savannas, with pointed leaves, and very slender stalks.

Native not only of Jamaica, but of Domingo and Cuba; flowering from october to february. Browne rightly perceiving that this plant did not properly conform itself to any known genus, constituted this new one of *Echites*, which is now universally adopted [m]. Dr. William Houstoun sent Mr. Miller the seeds before 1733.

7. Stems twining, shrubby. Leaves three inches in length. Common peduncles short, with difform pedicels. Flowers large, pretty, the tube purple, and the border green. It climbs trees to the height of twelve feet, and the whole plant is milky. Native of South America near Carthagena, flowering in october [n].

8. This is an elegant shrubby plant, not milky; with round, smooth, sarmentose stems; the older ones procumbent, and putting out roots, the younger suberect, and thickened at the joints into discoid knots. Common peduncles usually bifid, bearing elegant, tender, red flowers. Native of St. Domingo; flowering from october to december [o].

9. This climbs up trees with its twining shrubby stems twenty feet in height, and the whole of it abounds with a white glutinous milk. Leaves ovate, oval, or obovate, acute, numerous, two inches long, entire, smooth, shining above, pale underneath, stiffish. Racemes terminating, branched, spreading, red. Flowers numerous, small, red or purple. Teeth of the calyx very minute, coloured. Corolla cylindric, very short: border reflex, with sharp segments. Nectareous glands connate. Filaments from the bottom of the tube, longer than the corolla. Germ twin, pubescent; style with a very slight longitudinal groove on each side, by which it may be easily split in two: stigma within the cone of anthers. Follicles horizontal, reflex, roundish, obtuse.

tuſe, two-valved. Seeds oblong, with a briſtly down.

Native of the iſland of St. Domingo, flowering in november. In the mountainous woods of Hiſpaniola, flowering in the ſpring.

The French inhabitants call it *Gras de galle* [a].

10. This plant abounds in a white milk, and climbs the trees to the height of ſixty feet. Stems round, woody, pliant, twining, an inch in diameter, with alternate branches a foot and half long, at different diſtances, leafy their whole length. Leaves oblong, veined, ſmoothiſh, acuminate, diſtich, half a foot long. Spikes oppoſite, cloſe, an inch and half long, ſolitary, ſpreading, ſometimes, but rarely, divided in two. Flowers numerous, white, ſmall, ſubſeſſile. Native of Carthagena in New Spain, in thick lofty woods, flowering in july and auguſt [b].

11. This is a tree. Leaves lanceolate-elliptic, naked. Flowers axillary, peduncled, erect, the ſize of thoſe of Nerium or Oleander, funnel-form: border erect, terminating in linear tips longer than the whole corolla, a circumſtance in which it differs from all other known plants. Native of the Eaſt-Indies.

12. This alſo is a tree, the branches of which are leafy only at the joints; where there are five or ſeven oval-lanceolate leaves, which are coriaceous, and tranſverſely ſtreaked. A few peduncles are produced among the leaves, of the ſame length with them. The flowers are very ſmall. Follicles in pairs, a foot and half long, and therefore longer than any others that are known. Native of the Eaſt-Indies [c].

13. Leaves a foot long. Racemes bifid, peduncled, axillary. Calycine leaflets oblong, erect, concave. Tube of the corolla cylindric, longer than the calyx; ſegments of the border roundiſh, emarginate. Anthers connate, within the throat. Stigma obtuſe, ſurrounded by a ſharp ring. The nectary covers the germ with five ſmall ovate ſcales.

14. This is a tree yielding a milky juice. Leaves on ſhort petioles, a long ſpan and upwards in length, and ſharp. Peduncles axillary, divided into two branches, and theſe again into two ſhorter ſpikes, cloſely covered with flowers, and erect. Corolla large, white, with a large flat border. Stigma as in the genus Vinca. Follicles in pairs, divaricating. A decoction of the herb is a well known remedy at Surinam in the venereal diſeaſe. This and the preceding were obſerved at Surinam by Dalberg.

15. The filaments are bearded.

16. This and the preceding are very ſingular ſhrubs, much reſembling each other. They are ſucculent, milky and two-ſpiked. Without ſeeing the fructification they might be taken for Euphorbias. They are natives of the Cape of Good Hope, and were obſerved there by Thunberg [d].

17. Native of the Society iſles [e].

18. Stem twining, round, as are alſo the petioles; the rib, nerves, and edges of the leaves rough-haired. Leaves three inches long, a little narrowed towards the baſe, broader at top, cordate at the baſe, the ſinus being cloſed by the incumbent lobes; they are ſomewhat rugged, nerved, veined, having hairs preſſed cloſe ſcattered over both ſurfaces, but more copious, and a little longer on the rib and nerves, eſpecially underneath. Peduncles axillary, ſhorter than the leaf, rough-haired. Flowers approximating, alternate, on ſhort pedicels. Segments of the calyx lanceolate, attenuated, ſmooth. Corolla two inches in diameter, or a little more, with aſh-coloured hairs ſcattered over the outſide, but very thick in the tube where the filaments are inſerted. Style filiform, the length of the tube. Found in Cayenne by von Rohr [f].

19, 20, 21, 22. Native of the Weſt-India iſlands [g].

[a] Jacquin and Swartz obſ. [b] Jacquin. [c] Linn. mant. [d] Linn. ſuppl. [e] Forſter. [f] Vahl. [g] Swartz.

PROPAGATION AND CULTURE.

Theſe plants have not yet been introduced into cultivation in Europe, but being moſtly inhabitants of the Weſt-Indies, they will require the protection of the bark ſtove, and muſt be increaſed and managed in the ſame manner with the tender ſorts of APOCYNUM, which ſee.

ECHITES. See *Cariſſa*.]

ECHIUM. (Εχιον of *Dioſcorides*. Εχιον of *Nicander*. Echium of *Pliny*: παρα τους ὀχεις. *Being ſuppoſed to cure the bite of the Viper; or to have ſeeds reſembling a Viper's head.*)

GENERIC CHARACTER.

CAL. *Perianth* five-parted, upright, permanent; *diviſions* ſubulate, upright.

COR. one-petalled, bell-ſhaped. *Tube* very ſhort. *Border* upright, gradually widened, five-cleft, obtuſe; *diviſions* generally unequal: the two ſuperior ones longer; the *inferior* ſmaller, ſharp, reflex. *Throat* pervious.

STAM. *Filaments* five, ſubulate, length of the corolla, declined, unequal: *Anthers* oblong, incumbent.

PIST. *Germs* four; *Style* filiform, length of the ſtamens. *Stigma* obtuſe, two-cleft.

PER. none. *Calyx* grown ſtiffer, guarding the ſeeds in its cavity.

SEEDS four, roundiſh, obliquely acuminate.

OBS. E. lævigatum & Italicum *have corollas nearly equal. The ſtamens and ſtyle are different as to length.* R.

ESSENTIAL CHARACTER.

Cor. irregular, with the throat naked.

SPECIES.

1. Echium fruticoſum. *Shrubby Viper's Bugloſs.*
Lin. ſpec. 199. *fyſt.* 189. *Reich.* 1. 401. *hort. upſ.* 43. *Comm. hort.* 2. 107. *t.* 54. *Pluk. mant. t.* 341. *f.* 7. (Bugloſſum.)
Stem ſhrubby, leaves lanceolate, attenuated at the baſe, villoſe-ſtrigoſe, without veins, calycine leaflets lanceolate, acute.

[2. Echium candicans. *Hoary tree Viper's Bugloſs.*
Lin. fyſt. 189. *ſuppl.* 131. *Jacqu. collect.* 1. 44.
Stem ſhrubby, leaves lanceolate, nerved, they and the branches birſute, calycine leaflets oblong and lanceolate acute, ſtyles rough with hairs.

3. Echium giganteum. *Gigantic Viper's Bugloſs.*
Lin. fyſt. 189. *ſuppl.* 131.
Stem ſhrubby, leaves lanceolate, attenuated at the baſe, hairy, hairs very ſhort, bractes and calyxes ſtrigoſe, ſtamens longer than the corolla.

4. Echium ſtrictum. *Upright Viper's Bugloſs.*
Lin. fyſt. 189. *ſuppl.* 131.
Stem ſhrubby, ſtiff, branching, leaves oblong-lanceolate, hairy, corollas ſomewhat bell-ſhaped, ſtamens longer than the corolla.

5. Echium ſpicatum. *Spiked Viper's Bugloſs.*
Lin. fyſt. 189. *ſuppl.* 132.
Stems aſcending, very ſimple, flowers in ſpikes.

6. Echium argenteum. *Silvery Viper's Bugloſs.*
Lin. fyſt. 189. *Reich.* 401. *mant.* 202. *Berg. cap.* 40.
Leaves linear, birſute and whitiſh, patulous at the tip.

7. Echium capitatum. *Headed Viper's Bugloſs.*
Lin. fyſt. 189. *Reich.* 401. *mant.* 42.
E. hiſpidum. *Burm. prodr. p.* 5.
Stem hairy, flowers head-corymbed, equal, ſtamens longer than the corolla, leaves hiſpid.

8. Echium plantagineum. *Plantain-leaved V. B.*
Lin. fyſt. 189. *Reich.* 402. *mant.* 202. *Barr. ic.* 1026.
β. Jacqu. hort. 1. *t.* 45.
Root-leaves ovate, marked with lines, petioled.

9. Echium lævigatum. *Smooth-ſtalked Viper's Bugloſs.*
Lin. ſpec. 199. *fyſt.* 190. *Reich.* 402.
Stem even, leaves lanceolate, naked, ſcabrous about the edge and at the tip, corollas equal.]

Leaves linear-lanceolate, ſtem ſuffruticoſe procumbent, both hiſpid and hoary.
19. Echium glabrum.
Vahl ſymb. 3. 22.
Leaves linear-lanceolate, ſmooth above, callous-dotted beneath on the outſide, ſpikes alternate.
20. Echium roſmarinifolium.
Vahl ſymb. 3. 22.
Leaves petioled linear-lanceolate reflex at the edge, hairy underneath and hoary.
21. Echium ſphærocephalum.
Vahl ſymb. 3. 22.
E. capitatum. *Lamarck.*
Leaves linear-lanceolate ſtrigoſe, heads ſolitary terminating, branches ſmooth.

DESCRIPTIONS, &c.

Moſt of the ſpecies are herbaceous, ſome however are ſuffrutescent. The flowers are in ſpikes or

ſpike-panicled, in the ſpikelets the flowers all point one way.]

1. This riſes with a ſhrubby ſtalk two or three feet high, dividing at top into ſeveral branches. Leaves ſeſſile, hairy, light green. The flowers are produced ſingly between the leaves at the ends of the branches; they are of a purple colour, and in ſhape much like thoſe of the Cretan ſort. They appear in may and june, but the ſeeds do not ripen in England.

[Stamens not longer than the corolla[a].

Native of the Cape of Good Hope.—Cultivated in 1759 by Mr. Miller[b].

2. This is a handſome ſhrub. The ſtems and branches are woody and ſomewhat tomentoſe, marked with linear, tranſverſe ſcars from fallen leaves. Leaves a ſpan long, approximating, lanceolate-ſubulate, attenuated at the baſe to the inſertion where it widens, marked with lines above and veined underneath, the veins are very long and ſimple; towards the panicle they are imbricate and narrower at the baſe. Flowers in a conical panicle formed of many ſpikes at the ends of the branches. Spikes pedicelled, ſimple, pointing one way, bending inwards. Corollas among the ſmaller ones of this genus, ſubhirſute, blue. The whole plant is white, and as it were ſilvery, with a ſoft cloſe ſhagginess covering the whole, hardly excepting the corolla.

Native of the high rocks of Madeira; where it was found by Mr. Francis Maſſon[c].—Introduced in 1777[d].

3. A very lofty ſhrub, with woody, round, hoary, ſmooth branches. Leaves a ſpan long, and the breadth of a finger, ſcabrous, veined. Flowers pointing one way, and forming a very large, pyramidal, terminating thyrſe, conſiſting of long, ſpiked peduncles. Corollas obtuſe, nearly equal, white.

Found on the rocks of Teneriffe by Mr. Francis Maſſon[e].—Introduced in 1779[f].

4. This is diſtinguiſhed by the ſtiffneſs and uprightneſs of the ſtem, by its petioled oblong leaves, and by the hairs of the ſtem being turned downwards. Peduncles axillary at the top of the ſtem ſolitary, naked, with three-parted ſpikelets, contracted into a head at the tip. Corollas ſmall, blue, with the ſtamens ſtanding out.

Found by Maſſon on the rocks of Teneriffe[g].—Introduced in 1779. *Biennial.* Flowering moſt part of the year[h].

5. Root-leaves very many, a hand in length, lanceolate-linear, very hairy. Stems twice the length of the leaves, with a few ſmaller, alternate, hairy leaves. Spike terminating, nearly of a finger's length, compact. Calyxes hoary. Stamens longer than the corolla.

Native of the Cape of Good Hope[i].

6. Stem branched determinately. Leaves ſcattered, acute, bent outwards at the tip, hoary with white hairs.

Native of the Cape[k].

7. Stem woody, branched. Leaves lanceolate, with patulous, pellucid hairs, bulbous at the baſe, ſcattered over them. Flowers crowded cloſely into terminating heads. Corollas regular, funnel-form, ſcarcely larger than thoſe of Lycopſis. Stamens twice as long as the corolla; and ſtyle double the length of the ſtamens[l].

Native of the Cape. See n. 21.

8. Leaves above hairy, ſoft, hiſpid: root-leaves like thoſe of Plantain, very entire, large: ſtem-leaves lanceolate, ſeſſile. Stems hairy, with ſoft not ſtrigoſe hairs; brown dots under the hairs, as in the reſt, but minute. Corollas violet-coloured (not blue, as in *E. vulgare*, nor ſhorter than the calyx, as in *E. creticum*). Bractes between the flowers, half-cordate, the length of the calyx; not ſubulate, as in *E. vulgare*, nor longer than the calyx, as in *E. creticum*. Annual.

Native

Native of Italy [a].—It flowers from july to october.—Introduced 1776, by Monſ. Thouin [b].

9. Stems underſhrubby, a foot in height. Leaves ſmooth, except that they are ſcabrous with mucronate callous dots about the edge, along the keel, and at the tip above. Racemes from the axils of the upper leaves, pointing one way, and ſmooth. Calyx ſmooth. Corolla but little irregular. Stamens declined. Seeds muricate.

Native of the Cape of Good Hope [c].—Introduced in 1774, by Mr. Francis Maſſon [d].]

10. This riſes with an upright hairy ſtalk; the flowers are produced in ſhort ſpikes on the ſide of the branches; they are ſmall, and ſcarcely appear above the calyxes. Some plants have white flowers, others purpliſh. The calyxes are very hairy, and cut into acute ſegments.

[Stem erect, branched, very rough with hard bulbous hairs. The flowers are ſmaller than in E. vulgare, but like that irregular, always white, not blue. Stamens very long [e].

Lycopſis *Bauh. pin.* 255. which is variety β. of the *Species plant.* and ſuppoſed to be the Jerſey plant, has ſmaller corollas, hairy on the outſide, eſpecially towards the top, and more regular than in the plant of the South of Europe. Perhaps the difference may ariſe merely from ſituation [f].

The Pyrenean Echium, which is ſet down in Syſt. veget. as a variety of E. lævigatum, is more probably a variety of this. It is very like E. italicum, and is extremely hiſpid with white ſtinging hairs. Corolla not wider than the calyx, pale fleſh colour, not white, funnel-form, almoſt regular, twice as long as the calyx, pubeſcent on the outſide and paler. Filaments double the length of the corolla, deep red. Anthers blue. Seeds even, ſubtrigonal at top with a ſort of intermediate or inner toothlet, which is more produced than the reſt. This is E. maius et aſperius, flore dilute purpureo of Tournefort, inſt. 135. And, Lycopſis monſpeliaca, fl. dilute purp. *Mor. hiſt.* 384 [g].

11. Stem erect, about a foot high; radical leaves long and lanceolate, hairy, deepiſh green above, paler below and with a ſtrong back nerve: ſtem-leaves ſmaller and narrower: ſtem rough and covered with red points: ſpike of flowers about a foot long, conſiſting, as in the common Echium, of a great many ſeparate ſpikelets or ſmaller flowering ſpikes proceeding from the axle of the ſmall leaves, and at firſt coiled as uſual. Flowers rather ſmall than large, of a paleiſh red, and with nearly equal and ſomewhat triangular ſegments. Anthers pale blue.

Native of Hungary, where it grows in plenty [h].

12. Stem erect, eighteen inches or more in height, when young ſimple, but becoming branched. The whole plant is hiſpid. The ſtem frequently, and ſometimes the leaves are beautifully ſpotted with red. The hairs on the ſtem riſe from gloſſy purpliſh black tubercles. Root-leaves forming a tuft, near two feet-long, petioled. Stem-leaves ſeſſile, four or five inches long; all lanceolate, quite entire, ſcabrous and hairy on both ſides. Flowers numerous in ſpikes; thoſe of each ſpike pointing one way, and cloſely wedged together. Calyx fringed with white hairs. Corolla before it expands of a fine red, afterwards of a bright blue. The colour however varies, to pale red, and white; if the corolla be blue, the ſtems are blueiſh, the ſtamens purple, and the bulbs from which the hairs ſpring are blood-red; but if the corolla be pale red, then the other parts of the flower are of the ſame colour, and the hair-bulbs are yellow; and if it be white, all the parts of the flower are of that colour, and the hair-bulbs green. The outſide of the corolla is ſet with ſhort hairs, and is marked with five riſing ribs extending from the middle of each ſegment down to the baſe; the upper and lateral ſegments are rounded, the loweſt ſomewhat pointed. The filaments are red and longer than the corolla; ſometimes much longer, and ſometimes very little longer or barely equal to the upper ſegment; anthers gray. Style very hairy: germs embedded in a fleſhy receptacle.—It is a ſhowy plant, and if it were not common, would have a place in our gardens. It is biennial, and once in three years appears abundantly in the corn-fields of Cambridgeſhire, *&c.* where it is known by the name of *Cat's tail.* Bees are fond of the flowers, but their wings are apt to be torn by the ſtrong hairs [i].

That the *E. anglicum* of Huddon is the *E. vulgare* of Linneus cannot be doubted [k].

13. It reſembles the foregoing very much, but the corolla is of a violet-colour; the ſtem is more diffuſed; the ſtamens are not longer than the corolla; they are purple, but the ſtyle is white and hairy; the tube of the corolla is almoſt as long as the calyx: and the whole appearance is different [l].

The colour of the herb is a more pleaſant green, and it is not ſo hairy; the hairs alſo are more tender, and not tubercled at the baſe. The ſpike of the flowers is ſhorter and not ſo compact. The colour of the corolla is conſtant, not red at firſt, but always pale blue. The length of the ſtamens differs, ſo that one will equal the longeſt part of the corolla, and the reſt be longer or ſhorter than the oppoſite ſegment [m].

The whole plant is ſmaller and weaker than the foregoing, which frequently grows very ſtrong and large on walls, whereas this grows in corn-fields and on banks. The flowers are conſtantly ſmaller, and the ſtamens never exceed the corolla, which is unequal [n].

Stem a foot high, branching at the top and bottom. The hairs are ſofter, and ſome of them riſe from tubercles; theſe are hardly if at all diſcernible on the leaves, though they are on the ſtem where they are intermixed with ſhort hairs not riſing from tubercles. The calyx is very unequal, the ſegments broader than in *E. vulgare.* Corolla deep blue, half as long again as the calyx, at the bottom of the two upper ſegments beſet both within and without with ſcattered hairs [o].

It is thus deſcribed by Retzius—Root annual, ſimple, fuſiform. Stem branched, hiſpid, almoſt upright. Lower leaves lanceolate, obtuſe: upper oblong-cordate, acute: all hiſpid, the hairs not iſſuing from a tubercled baſe. Flowers racemed, pointing one way: raceme revolute, elongated; bractes lanceolate, ciliate, alternately lateral. Calyx ſubſeſſile with hairs ſcattered over it, diviſions linear-lanceolate, ſpreading. Corolla violet-coloured, ſtriated, irregular; the tube much ſhorter than the calyx, white half way up, thinly hairy. The lower ſtamens the length of the upper lip; the upper ones the length of the lower lip; the fifth ſhorter; all bowed towards the upper lip: filaments fleſh-coloured, the two longer naked, the reſt having a few long hairs ſcattered over them. Anthers ſmall, black. Style hairy, red, the length of the ſhorter filaments growing finally to the length of the corolla. Stigma bifid, ſlender. Seeds ſmall, dark-brown, dotted-ſcabrous.

I have little doubt but that this is Miller's firſt ſpecies.] He ſays, that the leaves of this are ſhorter and much broader than thoſe of the common ſort; the ſpikes of flowers much longer, and the ſtamens equal in length to the corolla, whereas thoſe of the common ſort ſtand out much beyond it.

[Monſ. Gouan ſuppoſes this plant to be no more than a variety of E. vulgare: and Monſ. Villars can ſcarcely think that his E. violaceum is the ſame with that of Linneus, and thinks it poſſible that it may be an intermediate ſpecies between the E. violaceum and italicum of Linneus. He ſays, that in his plant the leaves are wider, the ſtem branching,

[n] Woodw. Miſs. [o] Stokes in With.

the flowers red and more regular, and the ſtamens not appearing out of the corolla. The plant is very rough with white hairs, which give it a whitiſh colour, and it is much branched.

Native of Auſtria and Germany. In England, near Norwich.—Introduced 1780, by Caſimir Gomez Ortega, M. D. It flowers in july [a].

14. This has trailing hairy ſtalks about a foot long, putting out ſeveral ſide branches. Leaves lanceolate, hairy, about three inches long, and three quarters of an inch broad, ſeſſile. The flowers come out on ſlender ſpikes, upon long peduncles, from the axils; they are large, of a reddiſh purple, which turns to a fine blue when they are dried.

[Corollas deep red, with the tube ſhorter than the calyx. Filaments not longer than the ſhorter lip of the corolla, a little villoſe at the tip [b]. The pericarp conſiſts of four cruſtaceous, brittle nuts, reſembling grape-ſtones; on one ſide convex, with a raiſed furrow in the middle between two lateral tubers; on the other ſide angular; ſcabrous on all ſides with white bony dots, brown at the tip; they are appendicled at the baſe with an unperforated triangular area; on the outſide they are of a ferruginous ſmoaky colour, within they are black and very ſmooth; they are one-celled and without valves. Seeds ſolitary, ovate, long-beaked, ſomewhat compreſſed, of a bay colour [c].

Native of the Levant. It is a biennial, and flowers from july to ſeptember. Cultivated in 1683, by Mr. James Sutherland [d].]

β. This has branching ſtalks, a foot and half long, declining towards the ground, and covered with ſtinging hairs. Leaves four inches long, and not more than half an inch broad, pretty much warted, and hairy. The flowers grow in looſe ſpikes from the ſides of the ſtalks, and alſo at the ends of the branches, they are of a reddiſh purple colour, but not ſo large as thoſe of the preceding; and the ſtamens are longer than the corolla. This alſo, if different, is a native of the Levant.

[15. Root above a foot long, and two inches thick, mucilaginous and ſweetiſh. Stem about three feet high, an inch thick, pale green, hard, ſolid. Lower leaves fifteen or ſixteen inches long, and four or five inches wide, pointed, whitiſh green, ſatiny above, cottony underneath, with a ſtrong midrib; they diminiſh conſiderably along the ſtem, not being above half a foot in length: they are alſo leſs cottony than the former, and much more pointed. Branches about half a foot long; both they and the top of the ſtem rough with ſtrong hairs, accompanied by leaves about an inch and half in length. All theſe branches are ſubdivided into ſmaller ones, bending like a ſcorpion's tail, and loaded with flowers an inch and half in length, of a pale blue colour, with two red bands on three of the ſegments, on a bright purple ground. Calyx almoſt as long as the corolla, rough with very large hairs. Style almoſt as long as the corolla, ſlightly villoſe, and purple. The flower has no ſmell [e].

Found in the Levant by Tournefort.—Introduced in 1780, by Monſ. Thouin [f].]

16. The lower leaves of this are more than a foot long, and two inches broad in the middle, gradually leſſening to both ends, and covered with ſoft hairs. The ſtalks grow two feet high: the flowers are in ſhort ſpikes from the ſides of them.

Native of Spain and Portugal. [Introduced in 1731, by Mr. Miller [g].

17. Stems ſeveral, diffuſed, woody at the baſe, ſimple, a palm or more in height, ſoft at bottom, ſomewhat rugged at top, hoary with white hairs, preſſed cloſe, and placed on minute tubercles, the lower ones longer, the upper ones more diſperſed. The lower leaves from two to three inches long, crowded, linear, ciliate below, gradually widening towards the top, dilated at the baſe, embracing, obtuſe, hoary on both ſides with cloſe ſhort hairs placed on minute dots; the upper ones an inch long, and recurved. Spike terminating, pointing one way, hoary-haired. Bractes ovate-lanceolate, obtuſe. Corolla villoſe on the outſide. Stamens longer than the corolla.

Native of Egypt.

E. argenteum differs from this in having lanceolate leaves, attenuated outwards and acute, with ſpreading and more hirſute hairs.

18. Stems a palm in height, branched at bottom, covered with little whitiſh tubercles, crowded cloſe together, and having white rigid hairs on the top. Leaves ſeſſile, half an inch long, gradually ſmaller, rigid. Spike terminating, ſolitary: flowers at firſt crowded, but afterwards more remote. Bractes ovate. Corolla half an inch in diameter, hoary. Stamens longer than the corolla. Nuts ſmall, ovate, acuminate, muricate. It differs from the preceding in having procumbent ſtems, hairs that are longer, ſtiff and rough, not preſſed cloſe, and leaves narrow at the tip.

19. Branches ſcattered, a little compreſſed at top, purpliſh aſh-coloured with very ſlender appreſſed villoſe hairs. Leaves ſeſſile, firm, an inch long, even. Spikes from the upper axils, erect, few-flowered, two inches long. Bractes ovate-lanceolate, the length of the calyx. Calyxes hairy, with lanceolate ſegments, the ſame length with the tube of the corolla. Stamens longer than the corolla. It differs from E. lævigatum in having the branches a little villoſe, the leaves narrower, not at all callous about the edge, the calyxes hairy, and the flowers ſmaller.

20. Branches round, ſcarred, hoary with hairs. Leaves ſcattered, an inch long, reſembling thoſe of Roſemary, on the upper ſurface hairy and green, with a groove along the middle, and ſomewhat rugged. Petiole very ſhort. Raceme terminating, ſhort. Leaflets of the calyx linear, hairy. Corolla almoſt regular, half as long again as the calyx. The place of the four laſt is between the ſixth and ſeventh ſpecies.

21. Branches ſcattered, round below, angular above, towards the end villoſe and toothletted from the fallen leaves. Leaves ſcarcely half an inch long, ſeſſile, frequent, ſubimbricate, beneath having callous dots, above and on the edge having only ſcattered ſtrigæ. Heads globular, hairy, on ſhort peduncles, with ſmall flowers that are almoſt regular, and have ſtamens longer than the corolla.

E. capitatum differs from this in having the branches more hairy, the leaves three or four times as long, the heads of flowers on ſhort branches collected into a ſort of corymb, not ſolitary on lengthened ſpreading branches, as in this, and the calyxes hoary with abundance of hairs, which in this are fewer and more diſtinct.—This and the two preceding ſorts are natives of the Cape of Good Hope.

The place of the laſt is between the ſeventh and eighth ſpecies [h].]

PROPAGATION AND CULTURE.

1. It is propagated by ſeeds, when they can be obtained, which ſhould be ſown in pots filled with light ſandy earth ſoon after they are received. Theſe may be expoſed to the open air till the beginning of october, when the pots ſhould be placed under a frame, to guard them from froſt; but in mild weather, they ſhould have the free air, to prevent the ſeeds from vegetating till the winter is paſt; for if the plants come up at that ſeaſon, their ſtems will be weak and full of juice, and very liable to rot with damps; therefore it is much better if the plants do not come up till toward march, which is the uſual time of their appearing, when the ſeeds are not forced by warmth. When the plants are fit to remove, they ſhould be each planted into a ſmall pot filled with light earth, and placed under a frame to forward their putting out new roots; then they ſhould be gradually inured to bear the

[h] Vahl.

open

open air, and the latter end of may be placed abroad in a ſheltered ſituation, where they may remain till the beginning of october; at which time they muſt be removed into an airy glaſs-caſe, where they may enjoy the ſun and have free air in mild weather. During the winter ſeaſon theſe plants muſt be ſparingly watered; for as their ſtems are ſucculent, too much moiſture will cauſe them to rot. In the ſummer they ſhould be ſet abroad in a ſheltered ſituation, and treated in the ſame manner as other plants from the ſame country.

14. This is annual, and the moſt beautiful of all the ſorts. The ſeeds muſt be ſown every year where they are deſigned to remain; and the plants require no other culture but to keep them clean from weeds, and to thin them where they grow too cloſe. In july they flower, and their ſeeds ripen in five or ſix weeks after. The ſeeds of the other ſorts being ſown in the ſpring, will the ſecond ſummer after produce flowers and ſeeds, after which they ſeldom continue. They all delight in a rubbiſhy gravelly ſoil, and will grow upon the tops of old walls or buildings; where, when once they have eſtabliſhed themſelves, they will drop their ſeeds, and thereby maintain a ſucceſſion of plants without any care, and on theſe places they appear very beautiful.

5. Eclipta ſeſſilis. *Seſſile-leaved Eclipta.*
Swartz prodr. 114.
Stem erect, leaves ſlightly embracing ovate toothed, flowers axillary ſeſſile diſcoid.

DESCRIPTIONS, &c.

1. The herb is like that of *Coreopſis Bidens*. The leaves are marked with three nerves, and are in pairs remote from each other. The flowers come out two together alternately from the axils[a].

Stem ſhorter and thicker than in the fourth, ſlightly flexuoſe, hirſute with hairs not preſſed to the ſtem but horizontal; it is ſcarcely branched. Leaves narrower more apparently ſerrate, the ſerratures toothletted and unequal; they are veined, with three veins ſtraighter, the veins are hirſute, though the ſurface, like the upper one, be roughened with cloſe-preſſed hairs. Peduncles ſhort, either ſolitary or two, ſeldom three from the ſame axil. Calyx not hemiſpherical but ovate with broader ſegments[b].

It is thus deſcribed by Swartz—

Stem erect, round, a foot high, leafy, almoſt ſimple, hiſpid with hoary hairs. Leaves oppoſite, tooth-ſerrate, wedge-ſhaped, broad-lanceolate obtuſe, triple-nerved, hiſpid. Peduncles alternate, uſually in pairs, longer than the leaves, one-flowered. Flowers white. Calyx of five or ſix leaves; ſcales broad-lanceolate, two larger, ſomewhat hiſpid. Flowers diſcoid; of the diſk numerous, four-cleft, minute; of the ray very many, minute. Seeds angular, thickiſh, naked, without any pappus. Receptacle naked, not chaffy.

Native of the Weſt Indies; and of the Eaſt Indies, Cochinchina, &c. If E. erecta of different authors be the ſame plant, which may be doubted. Loureiro ſays that in the Cochinchina plant the leaves are not nerved, not properly ſerrate, nor ſeſſile; and that the flowers are not in pairs. He adds, that the juice is uſed for dying hair both of men and quadrupeds, whence the natives call it ink-plant.

Cultivated 1690, in the royal garden at Hampton court. It flowers from july to ſeptember, and is annual[c].—Linneus marks it as biennial.

2. Stem round, branching, leafy, rugged, a foot and half high, reddiſh with white dots. Leaves lanceolate oblong, acute, ſerrate, rugged, oppoſite, ſeſſile, from two to three inches long. Peduncles one-flowered, ſubterminating. Flowers whitiſh, having no ſmell. The whole has a green watery ſap, which turns black in the air, and may be uſed as ink. If it could be fixed, it would make a very fine dye. The negroes are ſaid to increaſe the blackneſs of their ſkin by this juice[d].

This reſembles the firſt ſpecies, but the ſtem has white dots ſcattered over it.—Annual, and a native of Domingo and Martinico[e].

3. *Root* annual. *Stem* two feet high, round, hiſpid, brachiate, and finally compound. *Leaves* oppoſite, acuminate, three-nerved, wrinkled, pubeſcent-ſcabrous, ſerrate. *Flowers* terminating, ſolitary, on very ſhort peduncles, the ſize of thoſe of *Stæſheckia*, and white: calyx of about eight leaflets, cloſe, and the length of the flower: ray of the co-

[a] Linn. mant. [b] Murr. prodr. [c] Hort. kew.
[d] Jacquin. [e] Linn. mant.

rolla ſhort, as in *Achillea*, with ſubtrifid petals; in the diſk four florets which are five or ſix-cleft: anthers black: ſtigmas recurved; ſeeds oblong, ſubtrigonal. Receptacle the length of the ſeeds.

Native of the Eaſt Indies[1].—It flowers in ſeptember and october; and was introduced in 1777, by Sir Joſeph Banks, Bart[2].

4. This is often erect, like the firſt ſort, with ſubſeſſile flowers, or however on very ſhort peduncles[3].

The flowers come out alternately in pairs. Calyx ſimple. Anther brown. Seeds awnleſs, muricate in four rows[4].

Native of the Eaſt Indies, Japan, Cochinchina, and the iſle of Tanna in the South Seas.—It flowers in auguſt, and was cultivated by Mr. Miller in 1759[5]. Alſo prior to that in the Eltham garden[6]. It is an annual plant.

5. This is an annual plant, native of Jamaica *.]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds, ſown upon a hot-bed in the ſpring; when the plants are fit to remove they ſhould be tranſplanted into a freſh hot-bed to bring them forward: they muſt be ſhaded till they have taken new root, and then treated as other tender annuals, being careful not to draw them up too weak. In june they may be taken up with balls of earth, and being planted in pots are to be ſet in a ſtove, where they muſt be ſhaded and watered, and where they muſt remain to flower well.

EDERA. See *Hedera* and *Rhus*.]

EDGINGS.

Theſe beſt and moſt durable plant for edgings in a garden is Box; which, if well planted, and rightly managed, will continue in beauty ſeveral years: the beſt ſeaſon for planting this, is either in the autumn, or very early in the ſpring; for if you plant it late, and the ſeaſon ſhould prove hot and dry, it will be very ſubject to miſcarry, unleſs great care be taken to ſupply it with water. The beſt ſort for this purpoſe is the Dwarf Dutch Box.

The edgings are only planted upon the ſides of borders next walks, and not (as the faſhion was formerly) to plant the edgings of flower-beds, or the edges of fruit-borders in the middle of gardens, unleſs they have a gravel walk between them; which renders it proper to preſerve the walks clean, by keeping the earth of the borders from waſhing down into the walks in hard rains.

It was alſo the practice formerly to plant edgings of divers ſorts of aromatic herbs, as Thyme, Savory, Hyſſop, Lavender, Rue, *&c.* But as theſe very ſoon grow woody, ſo that they cannot be kept in due compaſs, and in hard winters are often killed in patches, whereby the edgings are rendered incomplete, they are now ſeldom uſed for this purpoſe.

Some people make edgings of Daiſies, Thrift, Catchfly, and other flowering plants; but theſe alſo require to be tranſplanted every year, in order to have them handſome, for they ſoon grow out of form, and are ſubject to decay in patches; ſo that there is not any plant which ſo completely anſwers the deſign as Dwarf Box.

DESCRIPTION, &c.

Theſe are trees or ſhrubs; the leaves in ſome are ſmooth, in others ſcabrous, the flowers in panicles terminating and axillary *.

1. This is an upright tree, from twenty to thirty feet high, with an oblong thick head. Branches unarmed, roundiſh, ſubdivided. Leaves alternate, veined, blunt, about four inches long, on ſhort petioles. Panicles terminating, oblong, large. Flowers terminating, numerous, white, ſmall. Calyx five-parted, with minute ovate ſegments. Corolla a little larger than the calyx, with acute ſegments finally rolled back. Filaments longer than the corolla. Style ſcarcely ſhorter than the ſtamens, awl-ſhaped, bifid. Stigmas ſimple. Berry ſpherical, at firſt yellow, then black. Seeds two, hemiſpherical, two-celled.

Native of Cuba and Jamaica; flowering there in january and february *.

In Jamaica, where it is pretty common in the lower lands, and known by the name of *Baſtard Cherry-tree*, it riſes generally to the height of ſixteen or twenty feet: the berries are ſmall, and ſeldom exceed the largeſt of our European currents in ſize. They ſerve to feed poultry, and are ſometimes eaten by the poorer ſort of people *.]

Mr. Miller received the ſeeds from Jamaica in 1734. The plants grew to the height of eight or nine feet, and produced flowers but not ſeeds. He will not allow that it is Sloane's plant: the leaves in this being ſmoother, longer and more pointed,

[1] Linn. ſuppl. [2] Hort. kew. [3] Swartz. [4] Linn. [5] Hort. kew. [6] Dillen. * Swartz.

* Juſſieu. * Swartz and Jacquin. * Browne.

and

and the corymb of flowers much longer than in Sloane's plant.

[2. This tree has a trunk three or four inches in diameter, dividing almoſt cloſe to the ground uſually in three parts, which run up twenty-five or thirty feet high: theſe having put out a few ſimilar boughs in their progreſs, ſcarcely attain the length of ten feet before they are bowed back to the ground, and require ſupport from the boughs of the neighbouring trees: they have many very ſhort lateral branches ſcatteringly diſpoſed: their bark is aſh-coloured and ſmooth. Strong, woody, ſhort, very thick, awl-ſhaped ſpines are ſcattered over the trunk, principal boughs, and ſecondary branches; the oldeſt of theſe frequently put forth from their middle a perpendicular leafy branchlet of the ſame length with themſelves.

Leaves oblong, attenuated at the baſe, obtuſe, entire, ſometimes ſubrepand, ſhining, on ſhort petioles, three or four inches long, uncertain in their number, but uſually five or ſix from the ſame tubercle, falling off every year. Racemes ſhort, ſubcorymbed, branched, ſupported by awl-ſhaped ſtipules, from the centre of the tubercles, not unfrequently coming out before the new leaves. Flowers very many, ſmall, with yellowiſh corollas. The ſegments of the ſtyle may be regarded as a two-parted ſtigma, whence with a glaſs appears an opening to the germ itſelf. Fruit the ſize of a Pea and red.

Native of Carthagena in New Spain, flowering in auguſt, and bearing fruit in october. It is called there *Cacaracacara*, and differs much in habit from the preceding; they agree however in the flower, except in the calyx and ſtyle [c].

3. This is a ſmall inelegant tree, having an aduſt habit, in Curaçao often above fifteen feet high, in Martinico ſeldom five. Trunk unequal, with a chinky bark. Branches very many, irregular. Leaves alternate, petioled, quite entire, various; obtuſe, acute or emarginate; on rocks ſmooth, elſewhere rugged; differing in ſize; oblong, ovate, *&c.* Racemes corymbed, terminating. Flowers ſweet. Corollas white, with roundiſh ſegments. Anthers oblong. Calyx in the fruit cloven. Berries ſhining, ſaffron or orange-coloured, pulpy, ſweet, ſucculent, more quadrangular as they are larger; eaten by children and the natives [d].

Leaves exactly ovate, both ſurfaces ſmooth and level: the tube of the corolla is only the length of the calyx. This ſpecies is the connecting link between Ehretia and Cordia [e].

Native of the Weſt Indies, growing from the crevices of rocks, where there is no ſoil.

According to Dr. P. Browne, it grows in the Savannas of Jamaica, it is there called *Poiſon-Berries:* the French name it *Bois cabril batard.* It ſeldom riſes above fourteen or fifteen feet: the berries are of a ſaffron colour. Browne named it *Bourreria*, after Mr. Bourer, (or rather Beurer) an apothecary of Nuremberg, who was a great promoter of natural hiſtory.

Cultivated 1758, by Mr. Miller [f]; who received the ſeeds from Surinam.

[4. This is a ſmall tree fifteen feet in height; ſometimes erect, ſometimes ſupporting itſelf on other trees. Leaves ovate acute, very ſmooth, alternate, petioled two inches long. Racemes branched, ſubcorymbed, ſubterminating. Flowers having a ſlight degree of ſweetneſs, much larger than in the preceding ones. Corollas white, with heart-ſhaped ſegments. Anthers ovate and large. Berries green, four-cornered, ſlightly four-grooved, ending in a blunt point, without any pulp, becoming finally of a reddiſh black colour, dividing into four parts, with the ſeeds ſticking in them, and continuing a long time on the tree.

Frequent about Carthagena, in mountain woods, flowering from may to auguſt, and ripening the ſeeds in october [g].

5. Native of Hiſpaniola [h].]

[c] Jacquin. [d] Ibid. [e] Linn. ſpec. [f] Hort. knew.

PROPAGATION AND CULTURE.

Theſe plants are too tender to thrive abroad in England, where they require a moderate warm ſtove in winter; but when the plants have acquired ſtrength, they may be placed in the open air during the heat of the ſummer; but it ſhould be in a ſheltered ſituation; and when the evenings grow cold in the autumn, they muſt be removed into ſhelter.

They are propagated by ſeeds, when theſe can be obtained. Sow them in ſmall pots, plunged into a hot-bed. They may alſo be increaſed by layers, but theſe are long before they put out roots.

DESCRIPTIONS, &c.

1. This is an extremely beautiful ſmooth graſs.—*Root* fibrous, perennial. *Culm* erect, jointed, from a foot and half to two feet high: joints about five. *Leaves* ſheathing, enſiform; the lower ones a hand in length, the upper ones much ſhorter: diſk ſmooth; edge cartilaginous and crenulate, ſcabrous. *Panicle* oblong, conſiſting of fifteen or twenty flowers: peduncles capillary, looſe, flexuoſe, in threes, pairs or ſolitary, ſimple or ſometimes a little branched, growing thicker at the top. Flowers drooping; calycine glume coloured at the baſe, outer corolline glume violet, inner becoming pale. Bundles of violoſe hairs very white and ſhining. Nectary and filaments white. Anthers yellow.—Firſt obſerved at the Cape by Thunberg[a].

2. Lamarck confounds this with the foregoing ſpecies, from which it is very diſtinct[b].

3. *Root* fibrous, whitiſh. *Culms* many, erect, jointed, leafy, round, ſtreaked, very ſmooth. *Leaves* ſheathing, linear-lanceolate, acute, nerved, ſtreaked, ſmooth except about the edge, where it is ſcabrous: *ſheath* often the length of a joint, ſtreaked, ſmooth, ſomewhat ſwelled, contracted at top, and bearing a *ſtipule*, which is ſolitary, intrafoliaceous, erect, ſhort, multifid and jagged, brown. *Panicle* terminating, erect: branches crowded, more or leſs ſubdivided, ſmooth. *Peduncles* crowded or ſolitary, ſimple or divided, capillary, ſtraight, ſcabrous, thicker at the tip. *Flowers* upright, large, hermaphrodite, three-ſtamened: valves of the calyx keeled, much ſhorter than the corolla, nerved, ſhining, purpliſh, awnleſs, the outer ovate, acute, with ſeven nerves, the inner roundiſh, obtuſe with a dagger-point, and five-nerved: corolla pale green; the outer very long, ſtraight, the valves nearly equal and priſmatic, ſmooth at the baſe, or very ſeldom obſcurely wrinkled between the angles, towards the tip tubercled and hiſpid, dagger-pointed and pungent; the outer valve obovate, with a bundle of whitiſh violoſe hairs at the back of the baſe; the inner placed above the other, embracing the inner corolla, ovate, cut at the baſe and adorned there with a bundle of violoſe hairs on each ſide; the inner corolla oppoſite not contrary to the outer, much ſhorter, awnleſs, ſmooth; the outer valve ovate, cloſely compreſſed, ſharp, nerved, the inner much narrower, linear-lanceolate, membranaceous, with one or two keels along the back. Nectary none. Filaments very ſlender, equal: anthers ovate, bifid both at the tip and baſed, two-celled; as the germ increaſes they are torn from the filaments and raiſed on the ſtyles to the top of the flower. Germ oval, compreſſed, ſmooth: ſtyles two upright: ſtigmas crinite, whitiſh. Seed oval, naked. Obſerved at the Cape by Maſſon[c].

4. *Culm* ſomewhat branched, kneed, leafy. *Leaves* ſheathing, enſiform, ſtreaked, naked, ſcrabrous about the edge. *Peduncles* capillary, ſtraight, thickening at the end. *Flowers* three times ſmaller than in the firſt ſpecies, green: calyx ſcarioſe about the edge, the outer valve larger: corolla awnleſs, twice as long as the calyx; the outer more rude, acinaciform, valves nearly equal, triangular, the outer valve of an even ſurface not wrinkled, the inner cut out at the baſe, tranſverſely wrinkled at the baſe, no villoſe hairs; inner corolla contrary to the outer, valves very ſmooth, nearly equal, the outer a little broader, embracing the inner. Nectary very minute if any? Filaments equal: anthers two-lobed at the tip, the lobes divaricate. Germ very ſmall, ſmooth: ſtyle bifid, with two penciliform ſtigmas. Seed naked. Though the ſtyle appears to be ſingle at the baſe, yet it has two ſtigmas, as in the Graſſes and Oryza (Rice), after which it ſhould be placed, ſince it has a great affinity with it.—Sonnerat brought it from the Cape in the year 1776[d].

5. *Culm* very much branched, kneed, round, ſtreaked, ſmooth: branches alternate. *Leaves* ſharp, very ſlightly pubeſcent underneath, ſubciliate about the edge; ſheath a little ſhorter than the internode, ſtreaked, contracted at the top, and bearing a ſtipule, which is ſolitary, intrafoliaceous, upright, multifid-capillary, white, ending on both ſides in a membranaceous, half-mooned, horizontal, brown proceſs, ciliated with white briſtly hairs, and embracing the ſtem. *Peduncles* uſually in fours, one-flowered (very ſeldom two-flowered,) capillary, ſtraight, thickening at the tip, moſtly pointing one way. *Flowers* the ſame ſize as in the fourth ſpecies, upright, monoecious: valves of the calyx keeled, nearly equal, the length of the corolla, ſomewhat ſcabrous, ſtreaked, awnleſs, green at the baſe and on the back, coloured at the tip and about the edge red or white; the inner ovate, the outer a little narrower, and linear: corolla awnleſs, green, the ſurface flat and not wrinkled; the outer unequal, hairy on the outſide, the valves ſomewhat diſtant; the outer valve ſhorter, much narrower, linear, obtuſe with a point, but not mucronate or dagger-pointed, the inner ovate, obtuſe, compreſſed at the tip, ſomewhat ſcabrous, equal at the baſe, and not manifeſtly cut out there, embracing the inner corolla, there are no villoſe hairs at the baſe; the inner corolla equal, contrary to the outer, and ſmooth, the valves ovate-lanceolate, hollow, converging, cloſely connected at one edge, cheriſhing the genitals. Two white, entire, rounded liſtle membranes, between the calyx and the corolla, form the *nectary*. *Filaments* equal: anthers much larger than in the foregoing ſpecies, filling almoſt the whole cavity of the inner corolla, and at length ſtanding forth. There is no rudiment of a piſtil in the male flower. Piſtil in a ſeparate flower: germ oval, ſmall, ſmooth, ſurrounded with a few long, white briſtles, which perhaps are barren filaments; ſtyles two, ſhort, patulous, white; ſtigmas crinite, brown, ſtanding forth on one ſide of the flower between the inner corolla and the inner valve of the outer. Seed naked.—Brought from the Cape by Sparrman[e].

DESCRIPTIONS, *&c.*

1. A tree branching from the bottom, growing ſometimes to the height of three fathoms, with a trunk the thickneſs of a man's arm or thigh, elegant in its appearance, eſpecially from the ſilvery brightneſs of the leaves. Bark ſmooth, brown. Wood pale, prettily veined with gray and brown, but not hard. Branches and branchlets ſlender, frequent, alternate, ſmooth, unarmed, or having thorns eſpecially in young trees. Leaves petioled, in the more northern parts lanceolate, in the more ſouthern broader, rather obtuſe, and larger; ſilvery white underneath, on their upper ſurface hoary-greeniſh and ſhining very much. The flowers come out at the middle leaves of the ſmaller branches, uſually ſolitary or two together, ſometimes but very ſeldom three from each axil, in which caſe one or two are on ſhorter peduncles and barren, having no germ, though they have a ſtyle and anthers. The diviſions of the calyx (or corolla) are four, very ſeldom five, never more in the wild plant, (others ſay from four to eight): the anthers are placed at the baſe of theſe on very ſhort filaments. Style the length of the calyx. Drupe always ſolitary, oblong, hoary-white when young, thicker and yellowiſh when ripe, incloſing within a ſweet pulp a woody, gray, furrowed nut. In the deſerts near the Volga the fruit is hardly bigger than the berries of the Barberry, whereas in the more ſouthern parts it is the ſize of the cornelian Cherry[a].

Native of the ſouth of Europe, the Levant, near the Caſpian ſea, in the deſerts near the Volga, and the farther Tartarian deſert, and other parts of the Ruſſian empire in Aſia. It flowers there in may.—It was cultivated by Parkinſon in 1633[b].

2. Mr. Miller diſtinguiſhes ſpecifically the thorny and unarmed narrow-leaved Oleaſter. The latter, he ſays, is that which is moſt commonly preſerved in the Engliſh gardens. The leaves are more than four inches long, and not half an inch broad: they are very ſoft, and have a ſhining appearance like ſattin. The flowers come out at the footſtalks of the leaves, ſingly, or two, and frequently three at the ſame place; the outſide of the calyx is ſilvery and ſtudded, the inſide of a pale yellow; it has a very ſtrong ſcent. The flowers appear in july, and ſometimes are ſucceeded by fruit.

The thorny Elæagnus he takes to be the common ſort, which grows naturally in Bohemia, and of which he ſaw ſome trees in the curious garden of the famous Boerhaave, near Leyden. The leaves of this are not more than two inches long, and about three quarters of an inch broad in the middle; they are white, and have a ſoft cottony down on their ſurface; at the footſtalk of every leaf comes out a pretty long ſharp thorn, the leaves being alternate, the ſpines come out on each ſide of the branches. The flowers are ſmall, and have a ſtrong ſcent when fully open. They were both obſerved by Tournefort in the Levant.

[2. This has the appearance of the foregoing, but the leaves are twice as broad, ovate-oblongiſh, ſoft to the touch on both ſides, pale underneath, but neither ſurface ſhining or ſilvery[c].

In ſtature and manner of growth this tree reſembles a middle-ſized Willow, as it does alſo in the hoarineſs of its leaves and the diviſion of its branches. Bark gray, and cloven in the trunk. Small branches alternate, all white-tomentoſe. Leaves alternate, oblong-ovate and oval, quite entire, petioled, with a ſnowy hoarineſs underneath, and dotted-hoary on the upper ſurface, not ſhining, but ſoft. In the wild ſpecimens from Perſia, ſharp, ſtraight thorns are ſcattered variouſly over the branches, on the ſmaller twigs they are hoary all over and bear leaves: whereas the cultivated trees have no thorns. Flowers alternate, peduncled, ſolitary, extremely fragrant: calyx funnel-form, hoary on the outſide, the diviſions become reflex by age, and are obſcurely yellowiſh within. Stamens between theſe diviſions. Germ oblong; ſtyle the length of the calyx. Drupe ovate, very obſcurely octangular, tomentoſe: nut furrowed with a cylindric kernel.—This and the *ſpinoſa* of Linnæus do not ſeem to differ any otherwiſe than a garden tree does from a wild one, or the thorny variety of the foregoing ſpecies from the unarmed.

Native of the mountains of Perſia from Caucaſus to Derbent, about the Caſpian ſea abundantly, *&c.*[d] and of the Levant. Introduced in 1783, by Mr. John Græffer[e].]

[a] Pallas. [b] Hort. kew. from Ger. emac. [c] Linn. mant. [d] Pallas. [e] Hort. kew.

3. This

3. This rises with a woody stem to the height of eight or nine feet, dividing into many branches. Leaves silvery; with several irregular dark-coloured spots; they are alternate, and continue all the year.

[Root tuberous[f]. Stem shrubby, erect, three feet high, unarmed, branched. Leaves quite entire, tomentose. Flowers lateral, white, on one-flowered peduncles, several together. Drupe small ovate, containing one seed[g].

Native of the East Indies and China.]

Mr. Miller says, that it is rare at present in the English gardens; but that there were several large plants of it in the royal garden at Hampton-court, some of which produced flowers.

[4. An upright tree; branches and branchlets alternate, round, divaricate, upright, ash-coloured, scabrous with dots, the last twigs angular and whitish. *Leaves* alternate, petioled, entire; above naked, brownish, dotted with a middle longitudinal furrow; silvery underneath; from erect patulous, an inch and half in length: petiole furrowed above, scarcely a line long. *Flowers* not in the axils, but scattered over the last twigs, solitary and peduncled. Peduncle capillary, shorter than the flower.

5. Stem shrubby, little branched: branches and branchlets alternate, few, round, ferruginous-brown, spreading, scabrous with dots. *Leaves* from each bud many, alternate, petioled, entire, upright; above half naked with scaly silver dots, wholly covered with silvery scales underneath; unequal, about an inch in length: petioles capillary, a line in length. *Flowers* many, peduncled from a bud among the leaves. Pedunces capillary, loose, silvery, about an inch long. Calyx club-shaped, oblong.

6. Stem shrubby; branches and branchlets alternate, round, upright, ferruginous-brownish, scabrous with dots. *Leaves* from alternate buds many, petioled, patulous; rather naked above with silvery dots; underneath silvered all over; half an inch in length: petioles capillary, scarcely a line long. *Flowers* many from a bud among the leaves, in a kind of umbel, peduncled, drooping: peduncles capillary, nodding, scarcely a line in length. Calyx ovate. This approaches very near to the foregoing species.

7. Stem arborescent. Branches roundish, almost naked, brown: branchlets angular, reddish-ash coloured, scabrous with dots, alternate, from erect patulous. *Leaves* alternate, petioled, entire, from spreading erect; above green, smooth; underneath reddish-scaly with ferruginous dots interspersed, an inch and half in length: petioles semi-cylindric, channelled above, half an inch long. *Flowers* axillary, solitary or in pairs, peduncled, upright. Peduncle shorter than the flower, capillary.

8. An upright thornless tree; branches round, streaked, tubercled with the deciduous branchlets, ash-coloured, scabrous with dots, upright; branchlets angular, alternate, like the branches. *Leaves* alternate, petioled, entire, from erect patulous; above smooth, green, beneath silvery; an inch in length: petioles semi-cylindric, above channelled, upright, half an inch long. *Flowers* axillary, aggregate, peduncled, almost upright: peduncles four or more, the length of the flower. It differs from *E. orientalis* in having rounded-ovate leaves, silvery underneath; from *E. latifolia* in having the leaves more rounded, and the branchlets not being spinescent or becoming thorns.

9. An upright tree; a fathom in height, with a brown scabrous bark. Branches round, like the trunk, flexuose, leafless, spreading; branchlets alternate, like the branches, leafy, stiff, spinescent at the end, the extreme ones axillary, spinescent, very short, leafless. *Leaves* alternate, petioled, somewhat obtuse, entire; above smooth, green, beneath silvery with scales interspersed with ferruginous dots, from reflex spreading, an inch long, stiff: petiole half an inch in length. *Flowers* in the axils of the leaves, about two, distinct, upright: pedicles shorter than the flower.—It differs from *E. spinosa*, which Pallas thinks is only a variety of *E. orientalis*, in the branchlets becoming thorns; in the leaves being oblong and broader; the flowers two or three and larger.

This and the five foregoing species are natives of Japan[h].]

[f] Linn. zeyl [g] Loureiro. [h] Thunberg.

PROPAGATION AND CULTURE.

1. The first sort is extremely hardy, and is not injured by frost: it is not however of very long duration: young plants therefore should be raised once in three or four years, by seeds or layers.

[2. Requires the protection of a greenhouse.]

3. This sort requires a warm stove to preserve it in this country; for it is too tender to live in the open air, except for a short time in the warmest part of the summer. It may be raised from seeds.

[The other species have not yet been introduced into cultivation in Europe.

Palma oleosa. *Mill. dict. n.* 6.

DESCRIPTION, *&c.*

[Trunk erect, irregular from the stipes of the fronds, which continue a long time, and are longer the nearer they are to the frond. Fronds pinnate, with a rigid rib (or rachis) fifteen feet in length, for four feet below the leaflets armed at the edge on both sides with awl-shaped spines, the uppermost hooked and bowed back, the middle ones straight, the lowest patulous and twice as long as the rest: leaflets sword-shaped, acute, unarmed, folded back at the base, a foot and half long, and an inch broad. After these have fallen the rigid rib remains some time and resembles the spine. Spadix axillary, a foot long, much compressed, erect, divided into about fifty branchlets, five inches long, erect, the thickness of a finger, compactly spiked, imbricate and irregularly disposed, with triangular acuminate tips. The branchlets, except the tip, are wholly covered with small flowers, each having a small roundish bracte at the base, the lowest on each branchlet being much larger than the others, with

a lanceolate point. The flowers have a ſingular and very ſtrong ſmell, like Aniſe ſeeds mixed with Chervil leaves. Fruit larger than a pigeon's egg; the pericarp variegated with yellow, black and red, and ſo full of oil as to run out on being very ſlightly preſſed. Nut black, with longitudinal interrupted whitiſh ſtreaks[a]. Gærtner deſcribes the fruit as a berried drupe, ovate, ſmooth and yellowiſh, with a thin rind, and a thick, oily, fibroſe pulp, the fibres ſtiffiſh, and adhering very cloſely to the ſhell; which is ovate, contracted above, and has at bottom three holes, one pervious and two blind; it is obſcurely three-cornered, wrinkled, ſtony, thick, of a yellow ochrous colour. Seed globoſely conical, umbilicate beneath with an immerſed nipple in the middle, notted with depreſſed bowed ſtreaks, bay-coloured or cinereous-brown. The drupe varies in ſize and form, ſome being like a ſmall pear, others like a plum, others again ovate-oblong and attenuated at both ends, and ſome not larger than a Spaniſh olive.]

Mr. Miller ſays, that the leaflets are long, narrow, and not ſo ſtiff as moſt of the Palms; that the foot-ſtalks of the leaves are broad at their baſe, where they embrace the ſtem, diminiſh gradually upwards, and are armed with ſtrong, blunt, yellowiſh thorns, which are largeſt at their baſe. The flowers come out at the top of the ſtem among the leaves; ſome bunches have only male flowers, others female; the latter are ſucceeded by oval berries, bigger than the largeſt Spaniſh olives, but of the ſame ſhape; they grow in very large bunches, and when ripe are of a yellowiſh colour.

From this fruit the inhabitants of the Weſt India iſlands draw an oil, in the ſame manner as it is extracted from olives. They alſo extract a liquor from the body of the tree, which when fermented has a vinous quality, and will enebriate. The leaves are wrought by the negroes into mats, on which they repoſe.

It is called in the Weſt Indies the Oily Palm, and by ſome Negroes Oil; the fruit of this tree having been firſt carried from Africa to America by the Negroes. It grows in great plenty on the coaſt of Guinea, and alſo in the Cape de Verd Iſlands, but was not in any of the American colonies, till it was carried there by the Negroes, who now propagate it in great plenty.—[Jacquin alſo ſays that he has never ſeen this tree wild in America, and that the French call it *Palmier*.

Gærtner has ſet down another *Elæis*, which he names *melanococca*, from the blackneſs of the nuts. He thinks it may poſſibly be no more than a variety: the ſhell however is much ſmaller, and not ſo much bellied, but rather oblong, and ſuddenly contracted at the tip into an oblique dagger point; it is alſo thinner, and elegantly variegated on the outſide with teſtaceous ſtreaks, irregularly confluent, with other alternate ſtreaks like the others, but of a coal black; when broken it appears of a ſooty black colour. The ſeed is ovate-oblong and brown.

Jacquin alſo mentions another very thorny Palm, which has ſomewhat of the ſame habit with Elæis guineenſis, and is called in Martinico *Grigri*. The fruit is eatable, of an acid flavour, globular ſlightly depreſſed, acuminate by means of the ſtyle, ſcarlet and ſhining. The pulp is ſmall, red, ſoft and not fibrous, ſurrounded by a very thin pellicle. Nut brown, with three obſcure holes, from which run lines in a ſtellate order like veins over the whole ſurface. Kernel cartilaginous and hollow. The fruit is figured in amer. pict. t. 263. f. 89.

Another Palm occurs about Carthagena, called by the natives *Corozo*. They make both an oil and a butter of the fruit for domeſtic uſes. The pericarp is ſhining and yellow on the outſide, ſupported by a three-leaved calyx and a three-petalled corolla, permanent and ſhining; it is but little fibroſe, not thick and contains a pleaſant oil. Its form is ovate obſcurely three-cornered. Nut black and ſhining, of the ſame form, with three obſcure holes at the baſe. Kernel roundiſh, cartilaginous, very hard, ſolid, with the centre ſlightly cloven. The fruit of this is alſo figured in amer. pict. t. 263. f. 90.

Linneus (in mant. refers to the third Palm of Miller, which is the Macaw-tree of the Weſt Indies. See *Bactris* and *Cocos*.

PROPAGATION AND CULTURE.

It muſt conſtantly be kept in the bark-ſtove, otherwiſe it will not make and great progreſs. In about twenty years it will be too tall for moſt of our ſtoves. It is propagated by ſeeds, for the ſowing and management of which ſee *Palms* and *Phœnix*.

   Leaves alternate oblong tooth-ſerrate at top, racemes axillary, flowers one-ſtyled.
3. Elæocarpus Dicera.
   Lin. ſuppl. 266. *Vahl ſymb.* 3. 67.
   Dicera ſerrata. *Forſt. gen.* 80: which ſee.
   Leaves oppoſite ovate doubly-ſerrate, racemes compound, flowers four-ſtyled.
4. Elæocarpus copalliferus.
   Retz. obſ. 4. 27. *n.* 85. *Vahl ſymb.* 3. 67. *Rheed. mal.* 4. 33. *t.* 15. (Pænoe.)
   Vateria indica. *Lin. ſyſt.* 494.
   Leaves quite entire, panicle terminating.
5. Elæocarpus integerrimus.
   Lour. cochinch. 338.
   Leaves lanceolate quite entire, flowers heaped axillary.
6. Elæocarpus oblongus.
   Gærtn. fruct. 202. *Rumph. amb.* 3, 161. *t.* 102.

DESCRIPTIONS, &c.

1. Branches round, warted, ſmooth. Leaves petioled, three inches long, bluntly-ſerrate, ſmooth, nerved and veined. Racemes axillary; flowers diſtant[b]. Linneus obſerves, that they are ſimple, looſe, ſolitary, the length of the leaves, which have a double gland at their baſe[c]. According to

[a] Jacquin

[b] Vahl. [c] Fl. zeyl.

Retzius, the calyx has three, four or five ſharp keeled diviſions; and the corolla has three petals, cut in tripartite diviſions; the ſtamens twenty-five, with anthers terminating in cirrhoſe threads, and the germ very tomentoſe[a]. Linnæus affirms, that there are twenty ſtamens in the Ceyloneſe plant, eight in that from Java, and ſixteen in Burman's[b]; who ſays however that there are ſixteen when there are four diviſions of the calyx, and twenty when there are five. The deſcription under *Dicera dentata* belongs to this ſpecies.

2. Branches round, dotted, ſmooth, with pubeſcent branchlets. Leaves petioled, two inches long, ſharp at the baſe, ſmooth on both ſides, except on the midrib, nerved above, ſomewhat veined underneath. Petioles villoſe[c].

This is a native of the iſlands of the South Seas; and the preceding of ſeveral parts of the Eaſt Indies. The two ſpecies have been confounded.

3. Branches round, a little compreſſed at top. Leaves petioled, ſmooth, veined at top, two inches long. Racemes three inches long, erect[d]. Accoſding to Linnæus's ſupplement, it correſponds with the preceding in the ſtructure of the flower; but it differs in having four ſtyles, a berried four celled fruit, and two ſeeds in each cell. See *Dicera ferrata*.

4. Leaves large, ovate, coriaceous, very entire, with tranſverſe nerves. Flowers in panicles. Calyx ſuperior, the diviſions linear-oblong, obtuſe, tomentoſe on both ſides. Petals longer than the calyx, ovate, entire. Stamens forty or more; anthers filiform at the tip. Germ conic, ſtreaked, tomentoſe: ſtyle angular. Fruit a conic, fleſhy, reſinous, one-celled pome.—The long linear anthers terminated by cirrhoſe threads ſeem to furniſh a better character than the torn petals.—It yields the copal reſin, but of this there are ſeveral ſorts[e].

It is thus deſcribed by Vahl.—This is a lofty tree, with round branches, mealy-tomentoſe at top, and ferruginous. Leaves petioled, alternate, half a foot long and more, lanceolate, acuminate, rounded at the baſe, almoſt three inches broad, ſubcoriaceous, ſmooth on both ſides, above very finely marked with lines along the nerves, and with more obſcure oblique lines between the nerves, beneath having protuberant, alternate nerves. Petioles two inches long, round, thicker towards the leaf, mealy-villoſe. Panicle a foot long, ſpreading, mealy tomentoſe: partial peduncles roundiſh, alternate. Flowers on the outmoſt branches of the panicle, racemed, nodding. Calyx tomentoſe, hoary: ſegments obtuſe, villoſe within, hoary, ſubcoriaceous. Petals oblong, ſmooth, coriaceous, quite entire. Filaments ſcarcely any; anthers numerous, awl-ſhaped, with a groove on each ſide, whitiſh, divided at top into two briſtles, ſhorter than the corolla. Germ ſuperior, conical, one-third of the length of the corolla, hairy grooved and angular: ſtyle filiform, ſmooth. Drupe cylindric, two inches long, the thickneſs of the thumb, ferruginous and mealy, ſharp at the tip, and very blunt at the baſe.

Vahl obſerves, that Vateria of Linnæus agrees with Elæocarpus in the calyx, corolla, anthers, and fruit; and that they are the ſame, appears from the ſpecimen in Herman's herbarium. He does not find that the calyx is ſuperior, as Retzius affirms it to be.

Native of the Eaſt Indies.

5. This is a middle-ſized tree, with ſpreading branches. Leaves ſmooth, petioled, alternate. Flowers many, golden, ſweet-ſmelling. Calyx five-leaved, with lax leaflets. Petals lacerated, longer than the calyx. Germs ten, roundiſh, minute, placed round the baſe of the ſtyle. Drupe, ſmall, black, ſubovate, ſubacute, ripening ſingly, the reſt of the germs proving abortive.—Native of Cochinchina, where it is alſo cultivated on account of the ſweetneſs and beauty of the flowers[f].

[a] Retz. obſ. 4. p. 27. n. 86. [b] Fl. zeyl. [c] Vahl.
[d] Ibid. [e] Retz. [f] Loureiro.

6. Drupe berried, ſuperior, ovate-oblong or ſubcylindric, ſmooth, covered with a ſoft fleſhy bark; ſhell ſtony, oblong, muricate and curled, with irregular tubercles; having three ſpurious ſutures never opening, one-celled, teſtaceous. Seed oblong, attenuated to both ends, obſcurely three-cornered, ſerruginous[a].

Native of the Eaſt Indies.

Lin. ſyſt. 241. *Jacqu. icon. rar.* 1. *t.* 48.
E. indicum. *Gærtn. fruct.* 1. 274.
2. Elæodendrum Argan.
Retz. obſ. 6. 26. *n.* 29.
Branches ſpiny, leaves ovate obtuſe.

DESCRIPTIONS, &c.

1. A moderate ſized twiggy ſhrub or tree, a native of the Oriental regions; with the leaves ovate-lanceolate, ſmooth, ſometimes ſlightly waved, and ſometimes even a little inclining to a ſubſerrated appearance on the upper parts of the ſhoots. Flowers borne towards ends of the branches, ſtanding by twos and threes; of a pale green colour, ſupported on ſhortiſh pedicels, each of which ſprings from a ſomewhat longer common pedicel. The lower ſhoots, or thoſe neareſt the ground, appear to be ſomewhat procumbent, and have narrower and longer leaves in proportion than the upper ones; the nerves or midribs of theſe leaves are alſo of a reddiſh colour[b].

2. This is a middle-ſized tree, with ſhort thickiſh ſpines at the ends of the branches. Leaves ſolitary and in bundles, an inch long, petioled, quite entire, coriaceous: others decreaſe towards the petiole, ſo as to be almoſt ſpatulate. Flowers in the axils of the leaves and ſpines, heaped, ſeſſile. Calyx inferior; leaflets a little unequal, hirſute and brown on the outſide, with the edges ſmooth and whitiſh. Petals half-ovate, entire, greeniſh with white edges. Filaments longer than the corolla, compreſſed, faſtened to the baſe of the petals. Anthers ovate. Germ from an ovate baſe conical, hairy, terminated by a ſtyle the length of the ſtamens and a ſimple ſtigma. Drupe dry. Nut very hard and ſmooth, pale brown, divided longitudinally by a white line; and having a ſingle kernel in each cell.—The calyx and ſtyle abide after the petals are fallen, but are wanting in the fruit. One of the cells in the nut is generally abortive. It is called *Argan* by the Moors, who expreſs an oil from the fruit, which the Europeans uſe in a variety of works, and the Moors for the table.

Native of the woods of Morocco, whence it was ſent to Retzius by Profeſſor Schulten[c].

P. sylvestris malabarica, fol. acuto. fr. pruni facie. *Rais hist.* 1364.

Fronds pinnate, leaflets opposite.

DESCRIPTION, *&c.*

This Palm grows to the height of about fourteen feet, the trunk being covered with an ash-coloured crust, closely united with a very hard whitish wood. Pinnate leaves break out from the top of the trunk only, in a decussated order, the old ones dropping off as the young ones break forth. The midribs are green, smooth and shining, flat within, convex, without, with long stiff spines at bottom. Leaflets opposite, on short petioles, numerous, oblong-rounded, acuminate, close, smooth, of a shining green, closed at the base towards the inside, finely streaked longitudinally. The flowers are concealed in stiff, green, coriaceous spathes, they are small, several on the same peduncle; petals whitish green; stamens whitish, sanguinose.

They have no smell, but a rough taste. Fruits oblong-round, small, like a wild Plum, with a hard woody point at top, covered with the calyx at bottom, first green, then red, but when ripe of a reddish brown, or blackish and shining, covered with a thin rind that is easily broken, and having a whitish, sweet, farinaceous pulp within; the nut or stone is oblong, rufous, marked longitudinally with a deep furrow, and containing a whitish bitter kernel. The fruits grow on green, smooth, shining branches, near a yard long, and two fingers broad, flat, stiff and woody; whence a clear austere liquor flows when they are cut or wounded.

The poorer sort of people chew the nut in the same manner with the Areca nut, with the leaf of the Betel and quick-lime. The elephants are very fond of the fruit branches, which are very sweet. The leaves, fruit, *&c*, are very astringent, and are looked upon as powerful in stopping fluxes[a].

Native of the East Indies. Introduced about 1763, by John Blackburne, Esq.[b]

Sicyos fol. ternatis. *Gron. virg.* 2. 191.

Leaves ternate, gashed.

DESCRIPTIONS, &c.

1. This is probably an annual plant. Stems round, smooth, herbaceous, diffused, scandent, with tendrils bifid and lateral. Leaves very finely serrate, smooth underneath, somewhat rugged above, petioled, alternate, numerous. Peduncles of the male flowers axillary, solitary, many-flowered, spreading, almost the length of the leaves, racemed or subumbelled. Female peduncle from the same axil, solitary, one-flowered, short. Corolla white, without scent in the day, but smelling sweet at night. Fruit green, an inch and half long, having but little watery pulp, smelling like cucumber; when ripe it opens elastically with a very gentle touch, and disperses its seeds; or when approaching to maturity, if it be held some time in the hand closed, it will do the same. One valve is composed of the whole sides and the anterior part of the fruit, and is roundish two-lobed on one side, or like the figure 8: the back of the capsule forms the other, which is therefore oblong: this on the inside at the tip is furnished with a lanceolate appendix, highly elastic, furnished with about eighteen toothlets, to which as many brownish seeds adhere.

Native of Carthagena in New Spain, covering entire shrubs with its stalks, and flowering in october and november[c].

2. Capsule kidney-shaped, rough with hairs, two-valved, opening with a spring; and therefore of this genus.

Native of Virginia[d].

Leaves in whorls.

DESCRIPTIONS, *&c.*

Thefe are annual aquatic herbs, very low, and fpreading; the flowers axillary and very fmall. In the firft fpecies they have fometimes only three petals, and fix ftamens; in the fecond, there are fometimes no more than four ftamens[a].

1. A very fmall plant, hardly a fpan in length. Stems very tender, creeping; the fhoots erect, and leafy. Leaves ovate-lanceolate, quite entire, feffile at the joints. Flowers folitary, much fmaller than in the fecond fpecies, alternate, on very fhort peduncles at the axils of the leaves on the branches, and clofe to them on the ftem. Petals white, purpliſh or rofe-coloured: ſtyles none, ſtigmas very ſmall: anthers globular. Capſules ſmaller than in the ſecond. [b]

Native of Denmark, Sweden, Switzerland, Sileſia, France; in ditches and wet places: flowering in ſummer. Found by the Rev. Mr. Williams about the E. ſhore of Bomere pool, near Condover, Shropſhire.

2. Stem decumbent, creeping at bottom, then erect, pellucid, brittle, ſix or ſeven inches in length, branched, round, the thickneſs of a quill, at the lower joints thick ſet with roots hanging in the water, having at the reſt whorled, ſeſſile, entire leaves, four to ſix in a whorl, (eight to twelve, *Haller*) at top only three: the emerſed leaves ovate-lanceolate, the immerſed ones linear, or even (according to ſome) capillaceous, bright green, reflex. Flowers axillary, two or three ſeſſile: calyx very ſmall, greeniſh; petals three or four, white, a little larger than the calyx: ſtamens ſeven or eight, very ſhort[c]. Capſule a little flatted; the partitions growing to the axis and oppoſite to the ſutures of the valves. Seeds numerous, very ſmall, ſomewhat cylindric; marked with longitudinal ſtreaks, and tranſverſe ones much finer, in a beautiful kind of net-work, bent a little and aſh-coloured[d].

Native of Aboa, Leipſic, Sileſia, Switzerland, near Paris and Montpellier; in ditches. It flowers in June and July.]

ESSENTIAL CHARACTER.

SPECIES.

1. Elegia juncea.

Lin. Mantiſſ. pl. altera. p. 297.

DESCRIPTION.

This is a native of the Cape of Good Hope, and has the habit of a Ruſh: the ſtems are ſeveral, about a foot high, round, ſmooth, filled as it were like thoſe of a Ruſh; hard, ſtrong, very ſimple, ſcarce ſo thick as a quill, with a ſimple joint. There are ſcarce any leaves, but two or three leafy ſheaths towards the root, imbricated over each other, and of a brown colour; there is alſo a rudiment of a ſimilar ſheath towards the middle of the ſtem: the ſpathe is terminal, and divided into other interior ones, which[e] are alſo compound: the parts of fructification are not very eaſily made out, but are moſt clear in the female flowers[e].

DESCRIPTIONS, &c.

Stem ſomewhat woody; involucres three-leaved containing three calyxes, ſometimes large boat-ſhaped, in very looſe corymbs, and on long pedicels; ſometimes ſmaller in the ſhape of bractes and axillary, ſeſſile and in ſpikes[a].]

1. This ſends out from a perennial root many oblong rough leaves, which ſpread near the ground: between theſe, in the ſpring ariſes a branching ſtalk, little more than a foot high. The ſide-branches are ſhort, and generally terminated by two heads of flowers, each on a ſhort peduncle. The flowers are of a pale purple colour.

[Dillenius deſcribes it more particularly. Height commonly eighteen inches or two feet. Stem rigid, round and hairy, the thickneſs of the little finger at bottom. Leaves embracing, much wrinkled, hirſute with hairs over the whole ſurface, ſerrate, but the ſerrature frequently not very conſpicuous becauſe the leaves are ſo much wrinkled and bent. From the axils of theſe, towards the top, ſpring forth the flowering branches, terminated by leafy heads collected in bundles; each having two or three leaves under it, inſtead of a common calyx; in the boſom of theſe is the flower, the proper calyx of which conſiſts of many narrow, ſharped-pointed, pungent ſcales, and contains three, four, or five florets, very pale purple, tubular, commonly divided into five narrow ſegments. Seeds cylindric-compreſſed, crowned with dry white ſegments inſtead of a pappus.

According to Browne, it riſes generally from half a foot to three or four feet in height; and is generally adorned with a great number of flowers, gathered into pretty large heads, at the extremities of the branches. The ſeeds are of an oblong form, each crowned with five little briſtles. The common peduncles are very long, and terminate the branches; but at the ſeparations of them there is always a ſmaller head growing to the ſtem, without any ſupporter. It is ſuppoſed to be a native of both Indies; Mr. Miller received it from ſeveral parts of America. Browne ſays, it is frequent enough in many places, on the north ſide of the iſland of Jamaica. Vaillant gave this plant the name of Elephantopus, becauſe he took it to be the ſame with the Ana-Schovadi of the Hortus Malabaricus, which ſignifies the foot-ſtep of an elephant. The accurate Dillenius however is doubtful of this, and perhaps after all, the Eaſt-Indian and Weſt-Indian plants may be different ſpecies.

This is a perennial plant, and flowers at the end of ſummer, and beginning of autumn,] but rarely produces ſeeds in England.

[It was cultivated in the botanic garden at Cheſea in 1695[b].

Browne ſays, that it is accounted a good vulnerary, and much uſed in conſumptive caſes in the Eaſt Indies. The leaves are frequently uſed, inſtead of Carduus Benedictus, among the inhabitants of the French Weſt India iſlands.]

2. Root-leaves four inches long and three broad, having many tranſverſe nerves; they ſpread flat on the ground, and from among them riſes a ſtiff ſtalk, about a foot high, dividing into ſeveral branches, and terminated by two flowers, compoſed of ſeveral florets, incloſed in a four-leaved involucre, having two of the leaflets alternately larger than the two others. This involucre being longer than the florets, they do but juſt appear within the two larger leaves; and the flowers make little appearance. They come out in july, but the ſeeds never ripen in this country. It grows naturally in South Carolina; and frequently comes up as a weed in earth ſent over thence with other plants. [Linneus remarks, that it is very nearly allied to the preceding.

3. This generally riſes to the height of ſixteen or twenty inches, ſometimes more. The common receptacles of the flowers riſe ſingly from the axils of the upper leaves, and ſeem diſpoſed in the form of a ſpike, but there are ſeldom more than four florets in each. The ſeeds are crowned with four little briſtles[c].

At firſt coming up it has many leaves, five inches long, and an inch and half broad where broadeſt; beginning very narrow, they continue ſo for two inches, and end in a round point; they are hard, ſmooth, dark green, and indented about the edges. From among theſe a round, ſtrong, green ſtalk riſes, four feet high, with an embracing leaf at each joint: it has branches towards the top, ſtanding round at every joint, divided into others, which are beſet with ſmaller leaves. From the axils of theſe come out the flowers, without any peduncle, ſtanding in ſeveral green leaves. The corollets are white[d].

The flowers are in bundles, without any involucre, ſeſſile in the axils of the leaves, in form of ſpikes on the uppermoſt branches. Calyxes ſubcylindric, four-leaved, with as many awl-ſhaped, imbricate ſcales at the baſe, and four-flowered. Seeds oblong, attenuated downwards, compreſſed, ſtriated, having very minute, appreſſed ſulvous briſtles ſcattered over them, of a brown-ochrous colour. Egret briſtle-awned, toothleſs, having five or ſeven rays, two of which are lateral and very long, below the tip, having a double curvature, firſt downwards then up again; the others are ſtraight, ſhorter, ſometimes very ſhort: all are of a whitiſh ſtraw-colour, ſlightly widening at the baſe, toothleſs and ſmooth.

Linneus has called the corollets *ligulate*, whereas they are plainly tubular, equally and deeply five-cleft; he was perhaps led into the miſtake, from the two outmoſt ſegments being ſometimes glued together[e].

Native of Jamaica, Hiſpaniola, and Guiana.

4. Root large, oblong, whence riſes a ſingle, round, ſtriated, hollow ſtalk, about two feet high, having ſeſſile leaves ſet on it alternately; their lower part whereby they are joined to the ſtalk having a membrane incloſing it; they are about five inches long, and half an inch broad near the top where broadeſt, end round, are of a pale green colour, and wrinkled. Towards the top come out the flowers in a ſpike, ſeſſile, incloſed in an involucre of a few dry brown membranes: theſe are followed by ſmall channelled ſeeds, having much pappus on them[f].

[a] Juſſieu. [b] Hort. kew. [c] Browne. [d] Sloane. [e] Gærtner. [f] Sloane.

Native of Jamaica: Sloane found it about mount Diablo very plentifully.]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds, which ſhould be ſown on a hot-bed in the ſpring; and when the plants are come up, they muſt be tranſplanted into pots filled with freſh light earth, and plunged into a hot-bed of tanner's bark, obſerving to water and ſhade them until they have taken root; then you ſhould let them have a large ſhare of freſh air in warm weather, and they will require to be frequently refreſhed with water.

The firſt, having a perennial root, if it is planted in a pot, and ſheltered in the winter from froſt, may be preſerved ſeveral years, and will annually flower; but the ſecond ſort ſeldom continues longer than two years.

Spike erect, cloſe, ſpikelets in ſixes, ſix-flowered, villoſe, calyxes awl-ſhaped, ſmooth, longer than the ſpikelets.

DESCRIPTIONS, *&c.*

Glumes two or three in each tooth of the axis, two-valved (in *E. Hyſtrix* none), one or two-flowered, or more, often many-flowered, with two-valved calyxes. The glumes connected have the appearance of an involucre, or of a four or ſix-leaved glume, in two or three rows, with the calyxes diſpoſed in diſtinct ſpikelets[a].

1. *Leaves* reedy, glaucous or whitiſh, involute and mucronate, channelled and rigid. Stems two or three feet high and more, ſtrengthened by three or four joints. *Spike* tomentoſe, linears eight or nine inches long, as large as a full-ſized ear of wheat, but leſs compact. Spikelets two, ſtraight, two-flowered, awnleſs. Like *Arundo arenaria*, it prevents the ſea ſand from blowing about by means of its matted roots[b]. Dr. Withering conjectures that it may poſſibly admit of being made into ropes, as *Stipa tenaciſſima* is in Spain. It is perennial, frequent on the ſea-coaſt in many parts of Europe, and flowers from june to auguſt.

2. Stems tall, round and ſmooth: leaves moderately broad, and commonly diſtinguiſhed by a kind of glaucous powdery complexion on the under ſides. Spike pendulous, cloſe or contracted, with the ſpikelets by twos, and longer than the calyx: the awns are moderately long, and ſlightly flexuoſe[c].

Perennial. Native of Siberia. Flowering in june and july. Cultivated in 1758, by Mr. Miller[d].

3. This in its habit and whole ſtructure is extremely ſimilar to the E. canadenſis, but the ſpikes in this are nodding or deſcending: the ſpikelets in this are alſo ſix-flowered; in the other four-flowered: in this alſo the awns are leſs ſtraight, and a little flexuoſe, even while flowering; whereas in the other they are ſtraight: the calyx is as ſhort again as the ſpikelet[e].

Native of Philadelphia. Perennial.

4. This agrees in moſt circumſtances with the ſecond ſpecies, it differs however in theſe. 1. The ſpikelets are villoſe, not naked. 2. The involucres end in an awn longer than the ſpikelet itſelf, whereas in the other the awn is much ſhorter than the ſpikelet. 3. The lower ſpikelets are three together, but in *E. ſibiricus* they are no more than two. 4. The ſpikelets, when in flower, ſtand wide from the ſcape, whereas in the other they approximate to it. At the baſe of each floret, on the inſide of the ſpikelets, is a dot or ſpot of a rufous-brown colour. The leaves of this are blueiſh, eſpecially underneath, which is not the caſe in *E. ſibiricus*. The awns alſo of the corolla, when the ſeed is ripening, from ſpreading become reflex, which in the other ſpecies they do not. Native of Canada[f], and Virginia.

[a] Juſſieu. [b] Linn. ſpec. & ſuec. Lightf. Ray. [c] Gmelin. [d] Hort. kew. [e] Linn. amœn. [f] Linn. ſpec.

Introduced before 1699, by the Rev. John Baniſter. It flowers in july and auguſt, and is perennial[g].

5. Leaves bare of hairs underneath. Sheaths ſmooth. Spikelets five or ſix lines long: calyx three lines long: lowermoſt corolla four or five lines long; the outer valve ſending out from a bluntiſh point, an awn, from ſeven to nine lines long; inner valve lanceolate, juſt ſenſibly longer than the outer, which is bare of hairs, with the edges at the point membranaceous. Theſe latter circumſtances diſtinguiſh this graſs from *Feſtuca ſylvatica*, which it very much reſembles in its general appearance[h].

It differs from *Triticum repens*, in the root not being creeping; the ſpikelets longer, narrower and rounder, furniſhed with long awns; whereas in *Tr. repens* they are very ſhort, if any[i].

Linneus removed this from the genus *Triticum*, wherein he had firſt placed it, on account of the lower ſpikelets being in pairs. Schreber never could diſcern this. Krocker however affirms that it really is ſo in the Sileſian plants.

Perennial, growing in woods and hedges; as between Greenwich and Woolwich; about Croydon; Ripton wood, Huntingdonſhire, Stokenchurch woods, Oxfordſhire, &c. in the north frequent. It flowers in june and july.

6. *Culm* two feet high, ſmooth and even, with red joints. *Leaves* ſmoothiſh, or but little ſcabrous, with very ſmooth ſheaths. *Spike* like *E. ſibiricus*, but much more ſlender. *Involucres* alternate, four-leaved, ſhorter than the floſcules, ſubulate, three-flowered. *Floſcules* ſeſſile, in pairs, with a pedicelled one between them. *Awns* terminating, as long as the floſcules or longer, often flexuoſe. Native of Siberia[k].

7. In this ſpecies the ſpike exceeds that of an ear of common barley, and there are two ſeſſile involucres affixed to each denticulated axis or baſe: each of theſe involucres conſiſts of two rays, which are longer than the flowers, and thicker, and are terminated by a long awn[l].

Perennial. Native of Virginia. Introduced in 1781, by Mr. William Curtis[m].

8. Culm upright, ſtout, two feet high and more, having four or five joints. The leaf at each of theſe is about a ſpan in length, and a quarter of an inch or more in breadth; ſmooth to appearance, but roughiſh to the touch, eſpecially round the edges. Sheaths hairy. Spike narrow, two inches or more, and ſometimes near three inches in length, much narrower, more naked, leſs rough, and harder than in Wall *Barley-graſs (Hordeum murinum); the ſpikelets are ſtiffer and longer, the pedicels thicker, and the awns ſhorter, except that of the inner valve of the corolla, which is longer: the middle floret is rather larger than the two others, with an awn ſomewhat ſhorter. They are all ſmooth to the naked eye, but appear hairy with a magnifier[n].

It very much reſembles *E. virginicus*, but the leaves of the involucre are not ſcored, as they are in that. The florets, together with their awns, are longer than the involucre; they are two in number, whereas in that they are three[o]. The two leaves of the involucre proceed from an exceedingly ſhort pedicel, diſtinct from that of the floret; they are equal, and ſomewhat ſcored towards the end. Florets generally ſingle, but often two, and both fertile; the lower on an exceedingly ſhort pedicel; the upper on a pedicel nearly half its length, with the rudiment of a third pedicel at the baſe of the inner valve.—In ſtructure it is an *Elymus*, in habit it approaches rather more to the *Hordeum*: in truth it ſeems the connecting link between both[p].

Native of Germany, Switzerland, England, in woods, with us in a calcareous ſoil, as near Berkhamſtead in Herts; Marlow and Hambleton, in Bucks; Henley and Stokenchurch in Oxfordſhire;

[g] Hort. kew. [h] Stokes in Withering. [i] Pollich. [k] Linn. ſuppl. [l] Gron. virg. [m] Hort. kew. [n] Haller & Fl. ruſſ. [o] Linn. mant. [p] Stokes in Withering.

Ripton woods, Huntingdonſhire; rocks oppoſite Matlock baths; in the North frequent.—Perennial; flowering in June. It is a coarſe graſs, like moſt of thoſe which grow in woods; and like them is ſometimes drawn up to a great height.

9. Culm narrow, a foot high. Spike oblong. Partial involucres four-leaved, ſpreading very much, or reflex, the length of the florets with their awns. Spikelets in pairs, two-flowered; both florets awned, but the inner one ſmaller in all its parts. Native of Spain and Portugal, on the coaſts [1].—Annual. Flowering in july. Introduced in 1784, by M. Thouin [2].

10. Spike compounded of two ſpikelets at each tooth of the rachis. Spikelets four-flowered, with long awns. Two calluſes inſtead of an involucre [3]. —Annual. Native of the Levant. It flowers here in july and auguſt. Introduced in 1770, by M. Richard [4].

11. Culm the thickneſs of the middle finger. Leaves involute, ſtrict. Spike a foot and half long, almoſt two inches thick at bottom, attenuated at top, imbricate, with numerous ſpikelets, an inch long. Valves of the calyx keeled, hollow, a little longer than the ſpikelets. Florets diſtich, ſeven, the end one barren: outer valve lanceolate, ſtriated at the top, villoſe to the middle; inner linear, blunt, ſtattiſh within, hollow without. Rachis villoſe. Its country is unknown [5].

PROPAGATION AND CULTURE.

Lin. ſyſt. 166. *ſuppl.* 128. *Forſt. gen. n.* 8. *Cavan. biſp. t.* 65. *Lamarck encycl.* 2. 355.

Thyrſes terminating, ſeſſile, anthers pedicelled, leaves obovate, veined, (oblong-ovate, ending in a cuſp.)

3. Embothrium ſpecioſiſſimum.

Smith New Holl. 19. *t.* 7.

4. Embothrium ſilaifolium.

Smith New Holl. 23. *t.* 8.

DESCRIPTIONS, &c.

1. A handſome ſhrub. The flowers ſmall and red, in ſolitary umbels.—Native of New Caledonia [6].

2. The whole plant is ſmooth. Stem ſhrubby. Leaves ſcattered, having one nerve branching on both ſides, on ſhort petioles, dilated at the baſe, and reddiſh. Buds red, with lanceolate, reflex ſcales. Flowers in ſpikes, terminating. Corolla ſcarlet, tubular-incurved, with an anther lying in the broad end of each of the four petals. Germ ſuperior, oblong, terminated by a long linear ſtyle: ſtigma flat. Seeds in the follicle imbricate, with a ſharp wing. Found in Terra del Fuego by Forſter, and in the ſtraits of Magellan by Commerſon, who named it *Ivora*. Its common name is *Catas*. Several other ſpecies have been obſerved in Peru and Chili [7].

3. This is a magnificent ſhrub; a native of New Holland; it grows to the height of eight or ten feet, with ſeveral ſimple, wand-like, round branches, clothed with numerous large, alternate, bright-green leaves, from four to ſix inches long; obovate and blunt, but tipped with a ſmall point: they are more or leſs ſerrated on the ſides. The flowers grow in a very denſe ſimple head on the top of each branch, and the head is ſurrounded at the baſe with numerous lanceolate leaves, or rather bractes, conſtituting the involucre: theſe as well as the flowers themſelves are of a rich ſanguine red.

4. Native of New Holland. The ſtems, which are ſeveral, grow three or four feet high or more, and are upright, and alternately branched and have alternate leaves, which in ſhape much reſemble thoſe of the Peucedanum Silaus; the upper and lower leaves are, however, more ſimple: the flowers ſtand in a long looſe terminal ſpike, and are white, with the tips of the petals revolute [8].

EMERUS. See *Æſchynomene*, & *Coronilla*.]

EMPETRUM. (*Of Pliny, Εμπετρον of Dioſcorides. From ιν and πετρα, a rock; ſo named from the place of its growth.*)

Procumbent.

DESCRIPTION, &c.

[1. This differs from the following ſpecies in having the ſmaller branches pubeſcent; the leaves longer, ſomewhat ſcabrous on their upper ſurface, and channelled underneath[c]. Berry guarded at the baſe by the calyx, fleſhy, white, ſhining. Seeds two or three, ſeldom more, bony, on one ſide convex and obſcurely furrowed, on the other angular or flattiſh[d].—Native of Portugal.

2. A ſmall decumbent ſhrub. The outer bark deciduous, and of a brown colour, the inner yellow. Branches rough with the remains of the petioles. The terminating bud conſiſts of five membranaceous leaflets, hairy at the edge; this puts forth five little branches, of which four are in a whorl. The leaves are in fours; they are ſomewhat three-cornered, with a white linear keel, and petioled. Flowers axillary, ſeſſile, ſolitary, ſurrounded by a bracte reſembling an outer three-parted calyx. Calyx whitiſh. Petals purple. Filaments very long, and purple, with browniſh black anthers. The female is like the male, but the ſtem is redder; the leaves deep green, in fives; piſtil black. Berries brownish black[e], when ripe.—The colour and ſize of Juniper berries, marked at top with a ſmall round hole, protected at bottom with a whitiſh three-leaved calyx, and a red corolla of three petals; the fleſh is rather firm, and pale green, except that towards the circumference it is purpliſh: receptacle central, columnar, ſlender. From ſix to nine bony, pale-coloured ſeeds are placed round this in a ring, and fixed to it a little above the baſe[f].

Linnæus informs us that he once, and once only met with a plant which had hermaphrodite flowers. Profeſſor Jacquin has obſerved ſeveral with three, two, and even one ſtamen only; a few females, but no males; the ſtamens are very upright, ſtiff and ſtraight[g].

Native of the northern parts of Europe, generally in elevated ſituations, both on dry, barren, and mooriſh or boggy ſoils. In moors from the Baltic to the Eaſtern ocean, in Kamtſchatka, and the iſles towards America. In the mountains of Lapland, and at the mines of Fahlun it abides, when other plants have periſhed with the cold[h]. In Warwickſhire, Staffordſhire, Derbyſhire, and the northern counties of England, it is frequent; alſo in Scotland.

The Highlanders and children in Scotland eat the berries, but they are no very deſirable fruit; and taken in large quantities are ſaid to bring on a ſlight head-ache. The Ruſſian peaſants, however, eat them, and the Kamtſchadales gather great quantities of them to boil with their fiſh, or to make a ſort of pudding with the bulbs of their lilies. They are eſteemed antiſcorbutic and diuretic[i]. Groufe and heath-cocks feed upon them, and they give the excrement a tinge of purple. Boiled in alum-water they afford a dark purple dye: and boiled with fat they are ſaid to be uſed in dyeing otter and ſable ſkins black[k]. Cattle do not ſeem to browſe on this ſhrub.—Linnæus ſays that it flowers in april with the Elm: with us it flowers in april and may[l].]

PROPAGATION AND CULTURE.

Theſe little ſhrubs are ſeldom propagated in gardens unleſs for variety ſake; but they may be cultivated in ſhady places, and will thrive very well in gardens, where the ſoil is ſtiff. The plants ſhould be procured from the places where they grow naturally, for the ſeeds remain a year in the ground before they vegetate, and afterwards are very ſlow in their growth. If they are planted on a moiſt boggy ſoil in autumn, they will get roots in the winter, and will require no farther care than to clear them from weeds; for theſe low ſhrubs commonly grow upon the tops of wild mountains, where the ſoil is peaty, and full of bogs.

SPECIES.

1. Empleurum ſerrulatum. *Cape Empleurum. Ait. hort. kew.* 3. 340.
Dioſma unicapſularis. *Linn. ſuppl.* 155.

DESCRIPTION, &c.

This is a ſhrub, with wand-like, even branches. Leaves like thoſe of a willow, alternate, ſubpetioled, linear-lanceolate, even above, beneath longitudinally wrinkled, ſmooth, quite entire on the edge, but appearing to be ſerrate by pellucid dots. Peduncles few-flowered, lateral, much ſhorter than the leaves. Flowers ſmall, moſt of them male. Capſules uſually ſolitary, incurved, with a beak of the ſame length. In the habit and aril of the ſeed it reſembles Dioſma, but it has no corolla, and only a ſingle capſule. Firſt obſerved by Sparmann, at the Cape of Good Hope[m]. Introduced here by Mr. Francis Maſſon in 1774[n].

4. Epacris rosmarinifolia.
   Forst. fl. austr. n. 69.
   Shrubby; leaves linear, obtuse, rigid, sheathing; flowers solitary, lateral.

DESCRIPTIONS, &c.

These are all natives of New Zealand. The fruit of the first and second species is particularly described by Gærtner. The second is considered as comprehending two species by Forster.

1. Capsule superior, suburbinate, rounded-five-cornered. Partitions inserted in the middle of the valves, and corresponding with the depressed grooves on the outside of the capsule. Receptacle in each cell one, free, oblong, cylindric-compressed a little, with a curved peduncle from the axis of the fruit, and hanging down from its other end, covered all round with many minute seeds, which are linear-oblong, attenuated to both ends and ruscescent.

[a] Gærtner.

2. The fruit of this is a small, superior, juiceless spherical berry, terminated by a short awl-shaped style: the rind is coriaceous, thin and black: the pulp fungous, rather solid, white and five-celled. Receptacle in each cell one, filiform, short, inserted at one end into the axis of the fruit, at the other supporting two pendulous seeds; these are in pairs, small, ovate, attenuated upwards, plano-convex, ruscescent. The leaflets of the calyx are ovate, concave and permanent. The corolla is salver-shaped and shrivelling; the tube loose and longer than the calyx, the border short and five-parted. Style filiform; stigma simple.

It differs from Epacris in having a simple stigma, a berry for a pericarp, and seeds in pairs. Hence Gærtner makes this an *Ardisia*[a].

3, 4. Both natives of New Zealand[b].

EPERVA. See *Dimorpha*.]

EPHEDRA, (*of Pliny. From επι, by, and υδωρ, water; expressive of the place of growth. Linn. According to this derivation it should be* Ephydra. *The true derivation must be from εφιδρα, insessio.*)

[a] Gærtn. fruct.

[b] Forster.

DESCRIPTIONS, &c.

This genus is allied to *Equiſetum*, as well in its habit and ſheathed joints, as in its ſtaminiferous column; it is perhaps ſtill more nearly allied to *Gnetum* or *Solicornia*. It conſiſts of leafleſs undershrubs, with cylindric jointed ſtems and branches: at each joint there are ſmaller branches either oppoſite, or in whorls; the joints of theſe are ſheathed with a membrane two-cleft at top: peduncles from the ſheaths ſolitary or ſeveral, one or many-flowered. The aments probably are formed of the very ſhort joints; and the calyxes are to be regarded as little ſheaths crowded together'.

Theſe plants vary extremely. Some, in the ſouth of Europe, are only a hand in height, whilſt others are three feet high. Linnæus ſuſpected that the Siberian plant might not be ſpecifically different from this; and Profeſſor Pallas is decidedly of that opinion; he ſuſpects that Linnæus had received only imperfect ſpecimens from Siberia, and was led by them to make a ſecond ſpecies.—Pallas thus deſcribes it:—It is a *ſhrub*, varying wonderfully according to its ſtation, ſometimes a foot or eighteen inches high, ſometimes only a finger's height, or even lower; proſtrate or aſcending. *Trunk* fibrous-woody, often thicker than a finger, with ſome branches ſpreading on the ground, and others, which are ſhort and woody, riſing, and ſubdivided copiouſly into ruſh-like branchlets. Theſe are jointed, not at all ſucculent, ſufficiently tenacious, glaucous-green, a little ſubdivided, ſometimes more than a ſpan in length, and ſtraight, ſometimes curled in a ſpiral, particularly in dry ſituations. The joints do not readily ſeparate; the internodes are often an inch and half in length, very finely ſtreaked, cylindric, terminated at top by two membranaceous, pubeſcent, emarginate ſcales. The plants are never hermaphrodite, but frequently barren, eſpecially in a dry ſoil. The *male* plant is uſually taller, with the aments of the upper joints commonly in pairs, oppoſite, on a peduncle iſſuing from one of the ſcales. The *male aments* are ovate, compoſed of three pairs of ſcales decuſſatively imbricate, ſomewhat fleſhy, concave-rounded, greeniſh; in the boſom of each ſcale is a two-valved corolla, ſomewhat membranaceous, putting forth a ſtamen, ſtanding out beyond the ſcales, having ſeven or eight globular yellow anthers, in a kind of raceme. *Female aments* uſually ſolitary, larger, ovate-acute, compoſed of four pair of ſcales, the upper ones gradually ſmaller. Theſe ſcales, in a flouriſhing plant, when ripe, become turgid, ſucculent, and of a beautiful ſcarlet colour, having two ovate-acute, plano-convex, browniſh gray ſeeds between the upper and moſt ſwelling ſcales. In dry ſoils, the ſcales continue almoſt the ſame, juiceleſs, yelloviſh-gray when ripe, with immature fruits, which have uſually one ſeed only, and that barren.—It is found in moſt of the ſouthern parts of the vaſt Ruſſian dominions; is common from the Volga to the Lena, and ſouthwards to Perſia and India. The berries ripen in july and auguſt; they are ſweetiſh, mucoſe, and leave a little heat in the throat: they are eaten by the Ruſſian peaſants, and by the wandering hords of all great Tartary; the Calmucs and other Tartars alſo uſe them medicinally, in catarrhs, rheumatiſms, &c.

The European plant was cultivated here before 1570, by Matthias de L'Obel, and flowers in june and july. The Siberian was introduced about 1772, by Meſſrs. Kennedy and Lee, and flowers from ſeptember to november'.]

PROPAGATION AND CULTURE.

Theſe may be propagated by offſets, which the plants ſend forth in great plenty, for the roots creep under ground, and ſend forth ſuckers, which may be taken off to tranſplant in the ſpring. They love a pretty moiſt ſtrong ſoil, and will endure the cold of our ordinary winters very well in the open air. Some of theſe plants were formerly preſerved in pots, and were houſed in winter, but by later experience they are found to thrive better in the full ground.

Lin. ſyſt. ed. Gmel. 2. *p.* 611.

Mataiba guianenſis. *Aubl. guian.* 1. 331. *t.* 128.

DESCRIPTION, &c.

1. This is a tree fifty or ſixty-feet high, very much branched at top; the middle branches, or thoſe in the centre being the higheſt, and ſtanding perpendicular: the lower ones are more inclining and horizontal, and ſpread out to a great diſtance: they divide into many branchlets, furniſhed with alternate leaves, each of which is pinnated: the pinnules oppoſite, from four to ſix in number, entire, oval, pointed, of a ſmooth ſurface, and of a bright green: theſe pinnules or leaflets are ſometimes eight inches in length. The flowers grow from the boſoms of the leaves on long pedicels, divided at their extremities into ſeveral ſmaller ones: theſe flowers are very ſmall and white. This tree grows in the foreſts of Guiana, and there flowers in the month of october'.

* *Climbing.*

1. Epidendrum Vanilla. *Vanilla* or *Vanelloe.*
Lin. ſpec. 1347. *Reich.* 4. 34. *mat. med.* 195. *Swartz obſ.* 324. *Brown. jam.* 326. *Blackw. t.* 590. *Plum. ic.* 188. *Pluk. alm. t.* 320. *f.* 4. *Merian. ſurin. t.* 25. (Vanilla.) *Cateſb. car.* 3. *t.* 7. (Volubilis.)]
Vanilla mexicana. *Mill. dict. n.* 1.
[Lobus oblongus aromaticus. *Cluſ. exot.* 72. *Sloan. jam.* 1. 180.—arom. ſubfuſcus terebinthi cornicu-lis ſimilis. *Bauh. pin.* 404.
Volubilis ſiliquoſa mexicana, fol. plantagineis. *Raii hiſt.* 1330.
Leaves ovate-oblong, nerved, ſeſſile, cauline, tendrils ſpiral.
2. Epidendrum Flos aëris.
Lin. ſpec. 1348. *ſyſt.* 817. *Reich.* 4. 35. *act. upſ.* 1740. *p.* 37. *Kæmpf. amœn.* 868. *t.* 869. *f.* 1.
Stem columnar, ſomewhat branched, leaves lanceolate, petals linear, obtuſe.
** *Stem upright, leafy.*
3. Epidendrum tenuifolium.
Lin. ſpec. 1348. *Reich.* 4. 35. *Rheed. mal.* 12. *t.* 5.
Leaves on the ſtem ſubulate, channelled.
4. Epidendrum ſpatulatum.
Lin. ſpec. 1348. *Reich.* 4. 35. *Rheed. mal.* 12. *t.* 3. *Rudb. elyſ.* 2. 222. *f.* 7. *Rumph. amb.* 6. 941. *t.* 44. *f.* 1. (Angræcum).
Helleborine ampliſſimo fol. vario. *Plum. ſpec.* 9. *ic.* 180. *f.* 2.
Leaves on the ſtem oblong, alternate, obtuſe, veinleſs, lip of the nectary bifid and divaricate.
5. Epidendrum furvum.
Lin. ſpec. 1348. *Reich.* 4. 36. *Rudb. elyſ.* 2. 122. *f.* 8. *Raii ſuppl.* 590. (Thalia.) *Rumph. amb.* 6. 104. *t.* 46. *f.* 1. (Angræcum).
Cauleſcent; leaves imbricate, lanceolate; racemes axillary.
6. Epidendrum coccineum.
Lin. ſpec. 1348. *Reich.* 4. 36. *Jacq. amer.* 29. *t.* 135. *pict.* 109. *t.* 205.
Helleborine coccinea multiflora. *Plum. ſpec.* 9. *ic.* 180. *f.* 1.
Leaves on the ſtem enſiform, obtuſe, peduncles one-flowered, axillary, crowded.
7. Epidendrum ſecundum.
Lin. ſpec. 1349. *Reich.* 4. 36. *Swartz obſ.* 325. *Jacqu. amer.* 224. *t.* 137. *pict.* 109. *t.* 207. *Plum. ſpec.* 179. *ic.* 84. *f.* 1. (Ophrys.)—*ſpec.* 9. *ic.* 148. *f.* 1. (Helleborine.) *Jacqu.*
β. *E. anceps. Jacqu. amer. pict. t.* 208.
Leaves on the ſtem oblong, emarginate, ſtem compreſſed, ſpike directed one way, tube of the nectary length of the corolla.
8. Epidendrum lineare.
Lin. ſpec. 1349. *Reich.* 4. 36. *Jacqu. amer.* 29. *t.* 131. *f.* 1. *pict.* 108. *t.* 201. *Swartz obſ.* 326.
Helleborine tenuifolia repens. *Plum. ſpec.* 9. *ic.* 182. *f.* 1.
Leaves on the ſtem diſtich, linear, obtuſe, emarginate, ſtem ſimple, flowers terminating, in a ſort of ſpike, lip entire.
9. Epidendrum punctatum.
Lin. ſpec. 1349. *Reich.* 4. 36.
Helleborine ramoſiſſima, cauliculis & floribus maculoſis. *Plum. ſpec.* 9. *ic.* 187.
Leaves lanceolate, nerved; ſheaths imbricate; ſcape panicled, and corollas dotted.
10. Epidendrum caudatum.
Lin. ſpec. 1349. *Reich.* 4. 37.
Helleborine ramoſiſſima, caulibus & floribus maculoſis. *Plum. ſpec.* 9. *ic.* 177.
Leaves lanceolate, nerved, ſcape panicled, petals ſpotted, tailed, two very long.
11. Epidendrum ovatum.
Lin. ſpec. 1349. *Reich.* 4. 37. *Rheed. mal.* 12. *t.* 7. *Rudb. elyſ.* 2. 223. *f.* 4. *Raii ſuppl.* 590. *n.* 40.
Angræcum minus album. *Rumph. amb.* 6. 99. *t.* 43. *f.* 1.
Leaves on the ſtem ovate, acute, ſtem-cleſping, nerved, ſcapes panicled.
12. Epidendrum ciliare.
Lin. ſpec. 1349. *Reich.* 4. 37. *Jacqu. amer.* 214. *t.* 179. *f.* 89. *pict.* 110. *t.* 209.
Helleborine graminea, fol. rigidis carinatis. *Plum. ic.* 179. *f.* 2.
Leaves oblong, veinleſs; lip of the nectary three-parted, ciliate, the middle ſegment linear; ſtem two-leaved.
13. Epidendrum nocturnum.
Lin. ſpec. 1349. *ſyſt.* 818. *Reich.* 4. 37. *Swartz obſ.* 327. *Jacqu. amer.* 225. *t.* 139. *pict. t.* 210. *Cateſb. car.* 2. *t.* 68. (Viſcum).
Leaves oblong, veinleſs; lip of the nectary three-parted, quite entire, the middle ſegment linear; ſtem many-leaved.
14. Epidendrum cucullatum.
Lin. ſpec. 1350. *Reich.* 4. 37.
Helleborine flor. albis cucullatis. *Plum. ſpec.* 9. *ic.* 179. *f.* 1.
Leaves ſubulate; ſcape one-flowered; lip of the nectary ovate, ciliate, acuminate; petals elongated.
15. Epidendrum teres.
Lin. ſyſt. 818. *Thunb. jap.* 30.
Stem ſheathed, decumbent, leaves columnar.
*** *Scape naked, leaves radical.*
16. Epidendrum nodoſum.
Lin. ſpec. 1350. *Reich.* 4. 38. *hort. cliff.* 430. *act. upſ.* 1740. *p.* 36. *Swartz obſ.* 328. *Jacqu. amer.* 226. *t.* 140. *pict.* 110. *t.* 213. *Herm. par. t.* 187. *Pluk. alm. t.* 117. *f.* 6. *Sloan. jam.* 1. 251. *n.* 11. *t.* 129. *f.* 3. (Viſcum.
Leaf ſingle, ſubradical, ſpadix containing about four flowers.
17. Epidendrum carinatum.
Lin. ſpec. 1350. *Reich.* 4. 38. *act. upſ.* 1740. *p.* 36. *Pet. gaz.* 44. *f.* 10. (Bontia).
Leaves oblong, obtuſe, compreſſed, jointed.
18. Epidendrum aloifolium.
Lin. ſpec. 1350. *Reich.* 4. 38. *act. upſ.* 1740. *p.* 36. *Rheed. mal.* 12. *t.* 8. *Raii ſuppl.* 572. *n.* 46.
Leaves oblong, obtuſe, broader at the end.
19. Epidendrum guttatum.
Lin. ſpec. 1351. *Reich.* 4. 38. *act. upſ.* 1740. *p.* 37. *Sloan. jam.* 1. 251. *t.* 148. *f.* 2. (Viſcum.)

Helle-

Helleborine fol. carnosis carinatis & sulcatis. *Plum. spec.* 9. *ic.* 182. *f.* 2?
Leaves lanceolate, channelled, petals wedge-shaped, retuse.

20. Epidendrum juncifolium.
Lin. spec. 1351. *Reich.* 4. 39.
Helleborine maculosa, fol. junceis & sulcatis. *Plum. spec.* 9. *ic.* 184. *f.* 2.
Leaves subulate, furrowed, scape and petals dotted, lip without dots, dilated.

21. Epidendrum scriptum.
Lin. spec. 1351. *Reich.* 4. 39. *Rumph. amb.* 6. 95. *t.* 42. (Angræcum).
Leaves ovate-oblong, three-nerved, flowers racemed, spotted.

22. Epidendrum retusum.
Lin. spec. 1351. *Reich.* 4. 39. *Rheed. mal.* 12. *t.* 1. *Rudb. elys.* 2. 220. *t.* 5. *Raii suppl.* 588. *n.* 33.
Leaves linear, retuse at the end, in two rows, flowers racemed, spotted.

23. Epidendrum amabile.
Lin. spec. 1351. *Reich.* 4. 39. *Rumph. amb.* 6. 99. *t.* 43. (Angræcum).
Leaves broad-lanceolate, veinless, petals lateral, orbiculate.

24. Epidendrum cochleatum.
Lin. spec. 1351. *Reich.* 4. 39. *Ait. hort. kew.* 3. 303. *Jacqu. rar.* 2. *Catesb. car.* 2. *t.* 88. *Swartz obs.* 329.
Helleborine cochleato flore. *Plum. spec.* 9. *ic.* 185. *f.* 2.
Leaves oblong, double, smooth, streaked, growing on the bulb, scape many-flowered, nectary cordate.

25. Epidendrum tuberosum.
Lin. spec. 1352. *Reich.* 4. 40. *Lour. cochinch.* 523?
Helleborine purpurea, tuberosa radice. *Plum. spec.* 9. *ic.* 186. *f.* 2.
Leaves broad-lanceolate, nerved membranaceous, growing on the bulb, scape sheathed, nectary boat-form, bifid.

26. Epidendrum pusillum.
Lin. spec. 1352. *Reich.* 4. 40. *mant.* 491.
Leaves ensiform, somewhat fleshy, scape few-flowered.

27. Epidendrum ensifolium.
Lin. spec. 1352. *Reich.* 4. 40. *Lour. cochinch.* 524. *Smith. spicil.* 2. 22. *t.* 24. *Thunb. in Linn. transf.* 2. 327.
Limodorum ensatum. *Thunb. jap.* 29. *Banks ic. select. Kæmpf. t.* 3. *Kæmpf. amœn.* 863. (Ran.)
Stem round, even, leaves ensiform, petals lanceolate, lip lanceolate, recurved, dotted.

28. Epidendrum moniliforme.
Lin. spec. 1352. *Reich.* 4. 41. *act. upf.* 1740. p. 37. *Thunb. jap.* 30. *Kæmpf. amœn. t.* 864.
Stem round, jointed, streaked, necklace-form, naked, quite simple, leaves linear, acute.

29. Epidendrum ophioglossoides.
Lin. spec. 1353. *Reich.* 4. 41. *Jacqu. amer.* 225. *t.* 133. *f.* 2. *pict.* 110. *t.* 211. (See n. 75.)
Helleborine opioglosso similis. *Plum. spec.* 9. *ic.* 176. *f.* 3.
Stem one-leafed, flowers racemed, pointing one way.

30. Epidendrum rufcifolium.
Lin. spec. 1353. *Reich.* 4. 41. *Jacqu. amer.* 226. *t.* 133. *f.* 3. *pict.* 110. *t.* 212. *Swartz obs.* 331.
Helleborine rusci majoris folio. *Plum. spec.* 9. *ic.* 176. *f.* 2.
Stem one-leafed, flowers from the sinus of the leaf aggregate.

31. Epidendrum graminifolium.
Lin. spec. 1353. *Reich.* 4. 41.
Helleborine graminea repens biflora. *Plum. spec.* 9. *ic.* 176. *f.* 1.
Stem one-leafed, flowers from the sinus of the leaf in pairs.

32. Epidendrum capense.
Lin. syst. 819. *suppl.* 407.
Scape naked, leaves imbricate in two rows, linear, obtuse, flowers directed one way, horn very long.

33. Epidendrum fuscatum. *Brown Epidendrum. Smith spicil.* 2. 21.
Helleborine perpurea umbellata. *Plum. cat.* 9. *Ic. Burm.* 179. *t.* 184. *f.* 1?
Stems simple, leaves oval, peduncle terminating, elongated, scaly, lip of the nectary five-lobed, the middle lobe minute.

34. Epidendrum tripterum. *Triangular-fruited Epidendrum. Smith ic. rar. t.* 14.
Leaves from a bulb and from the root sword-shaped, stalks radical sheathed, many-flowered, germ three-winged, lip equal to the petals.

35. Epidendrum Barringtoniæ. *Large flowered Epidendrum. Smith ic. rar. t.* 15.
Leaves broad-lanceolate, nerved, arising from a bulb, peduncles radical, mostly single-flowered, lip fringed, column with a cover.

36. Epidendrum claviculatum.
Swartz prodr. 120.
Cerei affinis scandens planta aphylla. *Sloan. jam.* 2. 160. *t.* 224. *f.* 3, 4.
Stem climbing, round, branching, leaves fossile, half-stem-clasping, acute, concave, recurved, rigid.

37. Epidendrum ramosum.
Swartz prodr. 120. *Jacqu. amer.* 221. *t.* 132. *pict. t.* 202.
Stem very branching, suffrutescent, leaves linear, emarginate, racemes terminating, compressed.

38. Epidendrum nutans.
Swartz prodr. 121.
Stem simple, leaves ovate-lanceolate, nerveless, stem-clasping, spike terminating, nodding, lip of the nectary three-lobed, the middle lobe three-toothed.

39. Epidendrum umbellatum.
Swartz prodr. 121.
E. difforme? *Jacqu. amer. t.* 136. *pict. t.* 206.
Stem simple, leaves ovate, emarginate, stem-clasping, veinless, flowers terminating, umbelled.

40. Epidendrum anceps.
Swartz prodr. 121.
Leaves cordate-lanceolate, stem-clasping, horizontal, raceme terminating, compressed, ancipital, subflexuose, flowers distich, inner petals capillary, with a three-lobed lip.

41. Epidendrum rigidum.
Swartz prodr. 121. *Jacqu. amer.* 222. *t.* 134. *pict. t.* 204.
Leaves oblong, obtuse, sheathing, raceme terminating, compressed, ancipital, flowers distich, larger than the spathes, lip entire, cordate-ovate, acute.

42. Epidendrum diffusum.
Swartz prodr. 121.
Leaves oblong, stem-clasping, stem ancipital, paniele terminating, very much branched, diffused, lip entire, acuminate.

43. Epidendrum montanum.
Swartz prodr. 121.
Leaves lanceolate, flat, recurved, spreading, submembranaceous, raceme terminating, simple, flowers pointing one way, lip trifid.

44. Epidendrum ferrulatum.
Swartz prodr. 121.
Stems aggregate, subdipyllous, leaves lanceolate, keeled, ferrulate, raceme terminating, flowers distich.

45. Epidendrum teretifolium.
Swartz prodr. 121.
Leaves semicylindric, stem one-flowered, lip three-sided at the tip.

46. Epidendrum globosum.
Swartz prodr. 121. *Jacqu. amer.* 221. *t.* 133. *f.* 1. *pict. t.* 203.
Leaves cylindric, channelled, flowers terminating, subsolitary, lip ovate, acute, capsules globular.

47. Epidendrum fertularioides.
Swartz prodr. 122.
Stem filiform, creeping, jointed, leaves lanceolate, peduncles one-flowered from radicle sheaths.

48. Epidendrum testæfolium.
Swartz prodr. 122.
Stem creeping, leaves incumbent, elliptic, concavo-convex, keeled, flowers sessile under the leaves.

49. Epidendrum undulatum.
Swartz prodr. 122.
E. carthagenense? *Jacqu. amer.* 228 *t.* 133. *f.* 4. *pict. t.* 214.
Viscum. *Sloan. jam.* 1. 250. *t.* 148. *f.* 1.
Satyrium. *Brown. jam.* 326. 15.
Helleborine maculosa, &c. *Plum. ic.* 178. *f.* 2.
Leaves elliptic, acute, scape farmentose, very much branched, petals ovate, clawed, obtuse, lip dilated, emarginate, waved.
50. Epidendrum variegatum.
Swartz prodr. 122.
E. tetrapetalum? *Jacqu. amer. t.* 132. *pict. t.* 216.
Helleborine fol. carnotis carinatis? *Plum. ic.* 177. *t.* 182. *f.* 2.
Leaves lanceolate, keeled, channelled, cartilaginous-serrate on the edge, sheaths imbricate, scapes sheathing, with a simple raceme, lip cruciate, two lobed.
51. Epidendrum utricularioides.
Swartz prodr. 122.
Leaves lanceolate, marked with lines, flat, scape panicled, lip large, heart-shaped, horn very short.
52. Epidendrum triquetrum.
Swartz prodr. 122.
Leaves three-sided, cultrate, compressed at the tip, lanceolate, acute, scape simple, lip heart-shaped, ovate, sides emarginate.
53. Epidendrum sessile.
Swartz prodr. 122.
Leaves compressed at the base, broader at top, lanceolate-linear, obtuse, veinless, peduncles radical, very short, one-flowered.
54. Epidendrum flabelliforme.
Swartz prodr. 123.
Leaves compressed at the base, dilated at top, ovate-lanceolate, acute, flat, nerved, peduncles one flowered, elongated.
55. Epidendrum fubulatum.
Swartz prodr. 123.
Leaves awl-shaped, grooved, peduncles sheathed, radical, many-flowered.
56. Epidendrum satyrioides.
Swartz prodr. 123.
Leaves subulate-cylindric, scape few-flowered, corollas ventricose at the base in front.
57. Epidendrum tribuloides.
Swartz prodr. 123.
Leaves pedicelled, lanceolate, obtuse, emarginate, peduncles very short, capsules globose, echinate.
58. Epidendrum corniculatum.
Swartz prodr. 123.
Leaves pedicelled, wedge shaped, oblong, peduncles radical, one flowered, corollas acuminate, curved.
59. Epidendrum Lanceola.
Swartz prodr. 123.
Leaves pedicelled, lanceolate, acute, peduncles, from radical sheaths, two flowered.
60. Epidendrum anguftifolifolium.
Swartz prodr. 123.
Leaf linear, growing upon the bulb, scape panicled.
61. Epidendrum palmifolium.
Swartz prodr. 123.
Leaves broad-lanceolate, nerved, membranaceous, growing on the bulb, peduncles radical, sheathed, many flowered, nectary boat-shaped, entire, reflex.
62. Epidendrum altiffimum.
Swartz prodr. 123. *Jacqu. amer.* 229. *t.* 141. *pict. t.* 215.
Leaves lanceolate, growing on the bulbs, scape very much branched, farmentose, petals oblong, lanceolate, acute, lip obcordate, shorter than the petals.
63. Epidendrum fragrans.
Swartz prodr. 123. *Ait. hort. kew.* 3. 304.
E. cochleatum. *Curt. magaz.* 152.
Leaf broad-lanceolate, nerveless, growing on the bulb, scape many-flowered, abbreviated, lip heart-shaped.
64. Epidendrum sanguineum.
Swartz prodr. 124. *Sloan. jam.* 1. 250. *n.* 10. *t.* 121. *f.* 2. (Viscum). *Brown. jam.* 324. 3. (Satyrium).
Leaves in pairs, oblong, growing on the bulb, scape many-flowered, subflexuose, lip roundish, waved, emarginate, horn adnate.
65. Epidendrum labiatum.
Swartz prodr. 124.
Leaves radical, oblong, middle bulb solitary, one-leafed, scapes few-flowered, lip oblong, with a fleshy corpuscle growing to it at top.
66. Epidendrum polybulbon.
Swartz prodr. 124.
Stem creeping, bulb bearing, bulbs two-leaved, one-flowered, flower peduncled, lip heart shaped.
67. Epidendrum proliferum.
Swartz prodr. 124.
Caulescent, leaves distich, subimbricate ovate, bulbs from the sheaths of the leaves two-leaved, flowers axillary, sessile.
68. Epidendrum vestitum.
Swartz prodr. 124.
Stem leafless, imbricate all round with sheaths, roundish, bulb-bearing, bulbs growing on the leaf, flowers crowded from the sheaths of the stem.
69. Epidendrum vomiforme.
Swartz prodr. 124.
Caulescent, leaves growing on the bulbs, ovate-acuminate, convex, channelled, three-sided beneath, scapes from the bosom of the leaves.
70. Epidendrum echinocarpon.
Swartz prodr. 124.
Limodorum pendulum. *Aubl. guian.* 818 *t.* 322.
Stem compressed, decumbent, one-flowered, leaves imbricate all round, distich, ovate, capsules muricate.
71. Epidendrum trichocarpon.
Swartz prodr. 124
Stem compressed, round, rooting, leaves imbricate all round, distich, linear, capsules tomentose.
72. Epidendrum glaucum.
Swartz prodr. 124.
Stem compressed, almost upright, many-flowered, leaves imbricate all round, distich, broad-lanceolate, very smooth, glaucous beneath, capsules naked.
73. Epidendrum graminoides.
Swartz prodr. 125.
Stem creeping, compressed, many-flowered, leaves imbricate all round, distich, remote, linear, peduncles longer.
74. Epidendrum micranthum.
Swartz prodr. 125.
Stem one-leafed, leaf broad-lanceolate, raceme very long, filiform, flowers pointing one way, roundish, six cornered.
75. Epidendrum trigoniflorum.
Swartz prodr. 125.
E. opioglossoides. *Jacqu. amer. t.* 133. *f.* 3. *pict. t.* 211. (See n. 29.)
Stem one-leafed, leaf oblong lanceolate, raceme the length of the leaves, flowers mostly pointing one way, three-cornered.
76. Epidendrum racemiflorum.
Swartz prodr. 125.
Stem one-leafed, leaf ovate, raceme longer than the leaves, flowers pointing one way, inner petals ovate.
77. Epidendrum alpestre.
Swartz prodr. 125.
Stem one-leafed, leaf ovate-lanceolate, racemes loose, keels of the capsules muricate.
78. Epidendrum laxum.
Swartz prodr. 125.
Stem one leafed, leaf oblong, raceme the length of the leaves, inner petals awl-shaped, lip ovate, capsules naked.
79. Epidendrum ovale.
Swartz prodr. 125.
Stem one-leafed, leaf ovate, acuminate, raceme pressed close, many-flowered, petals roundish, the inner ones remote in front at the base, capsules pedicelled.
80. Epidendrum pulchellum.
Swartz prodr. 125.
Stem one-leafed, leaf roundish, acute, raceme loose, few-flowered, petals acuminate, ciliate, the inner one crested at the tip.
81. Epidendrum tridentatum.
Swartz prodr. 125.
Stem one-leafed, leaf ovate-acute, three-toothed at the tip.

tip, raceme many-flowered, flowers three-sided, acuminate, petals of the nectary erect, bowed inwards.

82. Epidendrum cochleariſolium.
Swartz prodr. 126.
Stem one-leafed, leaf orbiculate, concavo-convex, raceme few-flowered.

83. Epidendrum ſunale.
Swartz prodr. 126.
Leafleſs, filiform, rooting, peduncle two flowered, lip two-lobed, horn very long, awl-ſhaped.

84. Epidendrum filiforme.
Swartz prodr. 126.
Leafleſs, filiform, rooting, peduncles ſubtriflorous, lip ovate, horn very ſhort, headed at the lip.

85. Epidendrum concretum.
Jacqu. amer. 228.
Leaves radical, lanceolate, acute, nectary concrete with the petals.

86. Epidendrum Cebolleta.
Jacqu amer. 230. *t.* 131. *f.* 2. *pict. t.* 217.
Leaf radical, ſingle, awn-ſhaped, knot rooted, raceme compound.

87. Epidendrum ſpathulatum.
Retz. obſ. 6. 43.
Leaves biſarious, alternate, approximating, præmorſe, with a doubled tip, coriaceous, ſcarcely a foot long.

88. Epidendrum variegatum.
Retz. obſ. 6. 44. *Rumph. amb.* 6. 93. *t.* 41. *f.* 3?
Leaves alternate, ſpreading, ſheathing, ovate acute, three-nerved, waved, ſmooth, variegated.

89. Epidendrum Calceolariæ.
Retz. obſ. 6. 45.
Leaves biſarious, alternate, remote, ſpreading very much, awl-ſhaped, thick, ſmooth.

90. Epidendrum hexándrum.
Retz. obſ. 6. 45.
Leaves biſarious, alternate, ſpreading, a little ſeſſile, ending in ſheaths, ſomewhat remote, lanceolate, emarginate with a point rigid.

91. Epidendrum Ophrydis.
Retz. obſ. 6. 46.
Leaves alternate, ſheathing, from erect ſpreading, ovate, acute, quite entire, nerved, ſmooth, a little bulbed on the ſurface, membranaceous, ſhorter than the ſcape, ending in tubular, keeled, ſmooth ſheaths.

92. Epidendrum Supplex.
Retz. obſ. 6. 47.
Leaves crowded, ſword-ſhaped, ſheathing, compreſſed, quite entire, acute, ſmooth, fleſhy.

93. Epidendrum orchideum.
Retz. obſ. 6. 48.
Leaves biſarious, alternate, ſeſſile, ſpreading, lanceolate, quite entire, acute, ſmooth, fleſhy, rigid.

94. Epidendrum puſillum.
Retz. obſ. 6. 49.
Shoots in bundles, appreſſed, a ſpan long, racemes ſolitary, ſimple, upright, compreſſed, naked at bottom, twobletted towards the tip, ſmooth.

95. Epidendrum complanatum.
Retz. obſ. 6. 50.
Leaves alternate, ſeſſile, ſpreading, linear-moon-ſhaped, retuſe, ſmooth, upper ſurface concave, lower keeled, fleſhy.

96. Epidendrum clavatum.
Retz. obſ. 6. 50.
Leaves alternate, ſeſſile, ſpreading, a little linear-club-ſhaped, with two unequal teeth at the end, ſmooth, flat, having a large nerve, depreſſed above, permanent beneath.

97. Epidendrum fubulatum.
Retz. obſ. 6. 51.
Leaves alternate, erect, ſeſſile, awl-ſhaped, cylindric, ſmooth, acute; ſheaths obtuſe, margined, ſmooth, with minute dark-purple dots, ſhort.

98. Epidendrum nudum.
Retz. obſ. 6. 52.
Stem none, peduncles ſimple, one-flowered, with two or three ſmooth membranaceous tubular ſheaths, inveſting the younger peduncles with an oblique mouth, caducous.

99. Epidendrum tomentoſum.
Retz. obſ. 6. 53.
Leaves from the bulbs uſually four ſeldom two or three, alternate, almoſt erect, biſarious at the baſe, half-ſheathing the bulb, oblong, quite entire, acute, concave, recurved, at the tip, ſmooth, eight-nerved, fleſhy.

100. Epidendrum bidentatum.
Retz. obſ. 6. 54.
Leaves ſheathing each other, three or four, ſeldom five, ſword-ſhaped, biſarious, ſeſſile, quite entire, with two ſharp toothlets at the tip, ſmooth on both ſides, keeled at the back.

101. Epidendrum lycopodioides.
Retz. obſ. 6. 55.
Stems crowded at the roots, pendulous, ſimple, compreſſed, leaves alternate, biſarious, ſheathing one another at the baſe, preſſed cloſe above the ſheaths, lanceolate, acute, a little margined, ſmooth, fleſhy.

102. Epidendrum longiflorum.
Retz. obſ. 6. 55.
Leaves growing to the bulbs, ſolitary, ſubpetioled, erect, lanceolate-retuſe, margin quite entire, recurved, ſmooth, fleſhy, rigid, brittle.

103. Epidendrum Flabellum.
Retz. obſ. 6. 57.
Leaves ſolitary, one from each bulb, erect, petioled, lanceolate oblong, quite entire, emarginate, a little recurved, obſcurely nerved, ſmooth, fleſhy, rigid.

104. Epidendrum ſaaronicum.
Retz. obſ. 6. 58.
Leaves alternate, ſubbifarious, ſeſſile, ſpreading, lanceolate, flattiſh, above even, ſtreaked ſlightly, and having five more evident nerves, beneath ſmooth, with a ſmall groove along the midrib, but no ſtreaks, emarginate, fleſhy, rigid.

105. Epidendrum plantagini ſolium.
Retz. obſ. 6. 60.
Leaves biſarious, ſheathing each other, erect, linear-three-ſided, ſlightly channelled, ſharpiſh, ſmooth, fleſhy, narrow at the baſe next the ſheaths.

106. Epidendrum ſeſſile.
Retz. obſ. 6. 60.
Leaves ſcattered from ſeſſile bulbs, ſpreading, ſubpetioled, retuſe, above ſmooth, a little channelled, beneath convex, fleſhy.

107. Epidendrum Ellifolium.
Retz. obſ. 6. 61.
Leaves from the bulbs ſubpetioled, erect at the baſe, more ſpreading at the tip, linear-lanceolate, ſharpiſh, ſmooth, keeled at the back, membranaceous, ſcarcely riged.

108. Epidendrum Calceolariæ terreſtre.
Retz. obſ. 6. 63.
Leaves ſpreading, biſarious, ſeſſile, ending in ſheaths, oblong-lanceolate, quite entire, ſlightly and obliquely emarginate, above even, ſhining, beneath ſmooth, with from nine to fourteen nerves, rigid, the lower ones ſhort, broader, the upper longer, ſcarcely an inch broad.

109. Epidendrum Flos aeris?
Retz. obſ. 6. 64.
Leaves from bulbs, ovate-oblong, acute, flat, fleſhy.

110. Epidendrum triſte.
Forſt. flor. auſtral. n. 314.
Leaves cylindric, empty, ſheaths ſiſſuloſe, peduncles oppoſite the leaves, corymbed, perforating the ſheath, lip of the nectary entire, ſpatulate-heart-ſhaped.

111. Epidendrum criſpatum.
Forſt. flor. auſtral. n. 315.
Leaves cauline, round, filiform, ſubincurved, empty, ſeſſile, raceme quite ſimple, lip of the nectary with the middle ſegment revolute, waved, crenate.

112. Epidendrum equitans.
Forſt flor. auſtral. n. 316.
Leaves equitant, enſiform-compreſſed, keeled, acuminate, ſcape naked, raceme ſpiked, nodding, filiform.

113. Epidendrum Myoſurus.
Forſt. flor. auſtral. n. 317.
Leaves ſheathing at the baſe, obliquely divaricate, linear, obtuſe, channelled, ſcape naked, raceme ſpiked, nodding, filiform.

114. Epidendrum biflorum.
Forſt. flor. auſtral. n. 318.
Leaves diſtich, linear-lanceolate, acute, peduncles two-flowered, ſolitary, perforating the ſheaths of the leaves, lip of the nectary trifid, acuminate.

115. Epidendrum autumnale.
Forſt. flor. auſtral. n. 319.
Leaves cauline, lanceolate, nerved, crowded, ſheathing, peduncles terminating, ſcaly, panicled, lip of the nectary ereƈt, retuſe.
116. Epidendrum Faſciola.
Forſt. flor. auſtral. n. 320.
Leaves rooting, paraſitical, bundled, linear, waved, ſcapes ſeveral, racemed, lip of the nectary ſlipper-ſhaped, with a ſpur.
117. Epidendrum umbellatum.
Forſt. flor. auſtral. n. 321.
Runners creeping, leaves oval, fleſhy, petioled, petioles fixed into ovate angular-keeled apophyſes, ſcape rooted, umbel ſimple, one-ſided, loweſt petals elongated.
118. Epidendrum reſupinatum.
Forſt. flor. auſtral. n. 322.
Baſaala-poulou-maravara. *Rheed. malab.* 12. *t.* 27.
Leaves cauline, petioled, ovate, acuminate, quite entire, plaited, keeled, five-nerved, racemé ſimple, ſpiked, flowers inverted. lower lip of the nectary toothed.
119. Epidendrum Clypeoleum.
Forſt. flor. auſtral. n. 323.
Leaf radical, roundiſh, cordate, cowled at the baſe, reflex and ſharp at the tip, ſcape almoſt ereƈt, racemed, lower lip of the nectary orbiculate, emarginate, very large.
120. Epidendrum nervoſum.
Thunb. in Linn. tranſ. 2. 327.
Ophrys nervoſa. *Thunb. jap.* 27.
Scape angular, leaves ovate, nerved, lip entire, reflex.
121. Epidendrum ſtriatum.
Thunb. in Linn. tranſ. 2. 327.
Limodorum ſtriatum. *Thunb. jap.* 28.
Scape angular, ſmooth, leaves ſword-ſhaped, nerved, petals lanceolate, lip oblong, flat.
122. Epidendrum teſſelatum.
Roxb. pl. corom. 2. 34. *t.* 42.
123. Epidendrum præmorſum.
Roxb. pl. corom. 2. 34. *t.* 43. *Rheed. mal.* 12. *t.* 4.
124. Epidendrum pendulum.
Roxb. pl. corom. 2. 35. *t.* 44.

DESCRIPTIONS, *&c.*

The whole genus is obſcure in its character, differences and ſynonyms; for the flowers in dried ſpecimens can hardly be unfolded; the plants are cultivated with difficulty in gardens; and the ſpecies have not been ſufficiently deſcribed by authors who have had an opportunity of ſeeing them in America and the Eaſt-Indies, their native places of growth.

Linnæus had only thirty ſorts in his ſpecies plantarum, and the number was not increaſed in the twelfth and thirteenth editions of the ſyſtema vegetabilium. In the fourteenth edition of the ſame work, two only are added by Murray from Jacquin, who has eleven other new ſpecies in his Stirpium americanarum hiſtoria. Swartz has forty-nine from the Weſt-Indies, ſome of which are the ſame with Jacquin's. Retzius has twenty-three obſerved by Koenig in the Eaſt-Indies. And Forſter has ten from the iſlands in the South ſeas. The number of ſorts here regiſtered amounts to 124, and doubtleſs there are many more, ſince Dr. Smith, in his elegant works, has figured two ſpecies from Jamaica, which eſcaped the reſearch of the indefatigable Swartz. On a ſeverer ſcrutiny, however, ſome of theſe numerous ſpecies may turn out to be varieties, and others to be the ſame ſpecies repeated.

Jacquin remarks, that all his ſpecies, particularly the ſmaller ones, become by age more or leſs ceſpitoſe, and run over the bark of trees with their numerous roots, fixing themſelves into it with a conſiderable degree of firmneſs. They differ very much from each other in the ſtructure of the flower, more indeed than ſeveral of the different genera of this order; and might be diſtinguiſhed into ſeveral genera.—Linnæus's character of the nectary is by no means ſufficient to form an eſſential character; for it is horn-ſhaped, ovate, ſlightly keeled, pedicelled, &c. The corollas alſo have from two to five petals; the anthers are from one to eight, and the capſules differ in their form. They are, however, all paraſitical, and could not be divided into genera without difficulty, which after all would be too artificial: Swartz, therefore, has done better by caſting the genus into eight ſubdiviſions or ſections. 1. Climbing. n. 39. 2. Stem leafy, upright 40 to 49. 3. Stem creeping. 50, 51. 4. Stemleſs, with radical leaves. 52 to 62. 5. Leaves growing on the bulbs, 63 to 72. 6. Stem creeping, leaves imbricate. 73 to 76. 7. Stems one-leafed, 77 to 85. 8. Leafleſs. 86, 87.

Juſſieu obſerves, that the petiole of the leaves is ſometimes dilated into a bulb; and that the flowers are either in ſpikes or panicles, varying in their form.

1. The Vanilla is ſeparated from the other Epidendrums by Plumier, Juſſieu, Miller, and others.]

Stem trailing, ſomewhat like common Ivy, but not ſo woody, faſtening itſelf to whatever tree grows near it, by ſmall fibres or roots produced at every joint, by which it may receive nouriſhment, when cut or broken off from the root a conſiderable height above the ground. The leaves are as large as thoſe of the common Laurel, but not quite ſo thick; they are placed alternate at the joints, which are ſix or ſeven inches aſunder, and are of a lively green colour above, but paler underneath. The ſtems ſhoot into many branches, which alſo faſten themſelves to the boughs of trees, and thus riſe to the height of eighteen or twenty feet, ſpreading quite over ſmaller trees. The flowers are of a greeniſh yellow colour, mixed with white; and are ſucceeded by fruit ſix or ſeven inches long.

[Five diviſions of the calyx (or the corolla, as Linnæus calls it) are equal, large, and ſpreading, generally waving; the ſixth, which is the inner one, is rolled up into a kind of funnel, with an unequal border; the flowers are in looſe flexuoſe ſpikes, both axillary and terminating*.

The pods grow in pairs, are generally the thickneſs of a child's finger, and about five or ſix inches in length; they are green at firſt, then yelloviſh, and turn of a browniſh caſt as they ripen. The ſtalk is moderately ſlender, and throws out a long winding tendril oppoſite to each of the lower leaves, by which it ſticks to the branches, or bark of the tree; but after it gains the top, theſe become uſeleſs, and the place of each is ſupplied by a fellow leaf*.

According to Swartz, the ſtem is ſubparaſitical, climbing very high, rooting by means of ſimple fibres like tendrils, oppoſite to the leaves, ſubflexuoſe, leafy, ſubdivided at top, round, thick, ſucculent, ſmooth. Leaves ſeſſile, or half-embracing, or ſomewhat ſheathed, alternate, ovate, acuminate, half a foot long, entire, longitudinally nerved, very ſmooth, thick. Flowers peduncled, axillary, large, purple: peduncle axillary, ſolitary, one or two-flowered, ſhort; with a ſeſſile ovate leaflet or bracte under each flower. Siliques pendulous, half a foot long and more, ſmooth, one-celled, three-valved. Seeds roundiſh, black, ſhining.

The manner of growth and flowering, the ſize of the flowers, fruit, and lens-ſhaped, dark ſhining ſeeds, without any aril, diſtinguiſh this from the other ſpecies. Vanilla, with E. flos aeris and ciſviculatum, might be ſeparated from the genus Epidendrum*.

Native of South America and the Iſlands in old woods, in the moiſt ſhady parts of them.] In the bay of Campeachy, at Carthagena, the Caracca's, Honduras, Darien, Cayenne, &c. the fruit is gathered and preſerved. Cultivated by Mr. Miller in 1759.

When it turns of a yellow colour, and begins to open, they gather it, and lay it in ſmall heaps to ferment two or three days, in the ſame manner as is practiſed for the Cocoa or Chocolate pods; then they ſpread them in the ſun to dry, and when they are about half dried they flat them with their hands,

* Juſſieu. ᵇ Browne. ᶜ Swartz & Gærtn.

and

and afterwards rub them over with oil of Palma Chriſti, or of the Cocoa; then they expoſe them to the ſun again to dry, and afterwards they rub them over with oil a ſecond time, then they put them in ſmall bundles, covering them with the leaves of the Indian Reed, to preſerve them.

Theſe plants produce but one crop of fruit in a year, which is commonly ripe in may, fit for gathering, for they do not let them remain on the plants to be perfectly mature, becauſe then they are not ſo fit for uſe; but when they are about half changed yellow, they eſteem them better for keeping, than when they are changed to a dark brown colour, at which time the fruit ſplits, and ſhews a great quantity of ſmall ſeeds, which are incloſed within it. While the fruit is green, it affords no remarkable ſcent, but as it ripens, it emits a moſt grateful aromatic odour. When the fruit begins to open, the birds attack it and devour all the ſeeds very greedily, but do not eat any other part of the fruit.

The fruits which are brought to Europe, are of a dark brown colour, about ſix inches long, and ſcarce an inch broad; they are wrinkled on the outſide, and full of a vaſt number of black ſeeds, like grains of ſand, of a pleaſant ſmell, like Balſam of Peru.

The fruit is only uſed in England as an ingredient in Chocolate, to which it gives a pleaſant flavour to ſome palates, but to others it is very diſagreeable; but the Spaniſh phyſicians in America uſe it in medicine, and eſteem it grateful to the ſtomach and brain, for expelling wind, to provoke urine, to reſiſt poiſon, and cure the bite of venomous animals.

[The Spaniards, French, and Italians not only uſe the Vanilla to give Chocolate a delicate ſmell, and agreeable flavour; but alſo to perfume ſnuffs and other ſubſtances. It yields a great quantity of oil and volatile ſalt [a].]

Mr. Miller has another ſpecies, which he calls *Vanilla axillaris*, and diſtinguiſhes by its oblong, blunt, compreſſed, jointed leaves, and axillary flowers. It was ſent him from Carthagena in New Spain, where it grows naturally. It has a climbing ſtalk, ſending out roots from the joints, like the other, and mounting to a great height. The leaves, which come out ſingly at each joint, are oblong, ſmooth and jointed. The flowers come out from the ſide of the branches; they are ſhaped like thoſe of the great Bee-Orchis, but are longer: the helmet is of a pale pink, and the lip is purple. It flowered in the Chelſea garden, but lived only one year.

There are two or three varieties of the common Vanilla, differing in the colour of their flowers, and the length of their pods.

[2. The flowers reſemble a ſpider. It is a native of Java, and is paraſitical [b].—See n. 112.

3. Native of Malabar in the Eaſt-Indies.

4. Native of the Eaſt Indies. Compare Cateſb. car. t. 68 [c].—See n. 13.

5. Native of the Eaſt Indies. The ſynonyms of Rheede and Rumphius belong to different plants; for they differ in the form of their leaves, the ſize of their flowers, &c. [d].

6. This is an elegant paraſitical plant. Roots round, numerous, fibrous, aſh-coloured. Stems ſeveral, ſcarcely attaining to a foot in height; before theſe ſpring the flowers come forth in the axils of the root-leaves; they alſo come out from the axils of the ſtem-leaves ſucceſſively as the ſtems advance. On the ſides of the ſtems are alſo knots or little roundiſh, compreſſed, ſmooth, wrinkled, ſpongy, green bulbs, terminated by a leaf. Leaves both at the root and ſtem ſubenſiform, emarginate, obtuſe, entire, veinleſs, ſhining, thickiſh, ſomewhat flaccid, converging at the baſe, flat above, from four to eight inches long. Peduncles filiform, whitiſh, tender, two inches long, one-flowered, axillary, commonly in pairs or three together, with a few ſheathing ſpathes. Flowers void of ſcent, the whole, with the germ, ſcarlet, agreeing in character with E. lineare, n. 8. except that the petals are ovate-accuminate and concave. Lower lip of the nectary lanceolate-cordate, ſomewhat rigid, and almoſt upright. Anthers on each filament double, compreſſed. Germ linear, ſlender, much longer than the petals.

Native of Martinico, in moiſt woods, eſpecially by the ſide of torrents [e]; alſo in Jamaica, but not common. Cultivated at Kew in 1794.

7. Paraſitical. Roots fibrous, white. Stem round at bottom, gradually compreſſed, leafy, pendulous. Leaves ſeſſile, ſheathing, alternate, ſpreading in two rows, the outmoſt tip emarginate, veinleſs. Peduncle ſcape-form, often two feet long, terminating, compreſſed, jointed as it were by the deciduous ſheaths. Flowers terminating, in form of a corymb, nodding one way, pale red or brown. Spathes minute. Three of the petals ovate-lanceolate, ſpreading, two linear, bent down. Nectary longer than the petals: lip three-lobed, the middle lobe emarginate, aſcending, ſpreading, the ſide ones ſmaller, emarginate. Column ſhort, bifid at the tip, bearing two pedicelled anthers under a two-celled lid, and concealed within the tube of the nectary. Stigma in front, funnel-form. Capſule oblong, angular, three-valved.

It varies with a rounder and more compreſſed ſtem; leaves broader, or more acuminate; flowers terminating, or breaking out on the ſide; and tube of the nectary ſhorter or longer than the petals [f].

Native of Martinico and Jamaica, in mountainous woods. Cultivated at Kew in 1794.

Swartz is of opinion that E. anceps of Jacquin is no more than a variety of this. Jacquin thus deſcribes it. Paraſitical, half a foot high, or ſomewhat more. Roots fibrous, round. Stem compreſſed, ancipital at top, with few leaves. Leaves oblong, blunt, coriaceous, alternate, ſheathing. Spadix lateral, few-flowered. The flowers have the ſame character with E. difforme (ſee n. 42), but the tube of the nectary is little more than half the length of the petals, and the lower lip is half three-lobed; *the lobes rounded*, almoſt equal, the middle one ſlightly two-toothed. Germ equal to the petals. Native of Martinico.

8. Paraſitical. Roots filiform, creeping, ſtrict, white. Stems ſimple, heaped, tufted, from one to two feet long, erect, filiform, leafy, compreſſed a little, ſmooth. Sheaths radical, withering, whence the ſtems appear to be jointed. Leaves alternate, approximating, ſeſſile, ſheathing, ſlightly ſtreaked, ſmooth on both ſides. Sheaths of the leaves compreſſed. Spike ſcarcely the length of the leaves: flowers ſeſſile, alternate, imbricate, from ſix to ten, ſmall and blood-red. Spathes ſheathing, under the flowers, coloured. Corolla three-cornered, gibbous at the back; the three outer, and the two inner petals almoſt equal, oblong, concave, blunt, the two outer in front vaulted, compreſſed at the tip. Nectary of the ſame ſhape with the inner petals, erect, embracing the column at the baſe, having two dark-purple ſpots at the edge, concave, blunt at top, blood-red. Column ſhorter than the petals, gibbous at the back, with three teeth at the tip, bearing in a cavity four oblong pedicelled anthers, cloſed by a four-celled lid, hollowed in front for the ſtigma. Capſule oblong, three-valved, opening in the middle. Seeds extremely minute, duſty and briſtly [g]; as Jacquin ſays, irregularly ſhaped like ſaw-duſt.

Native of thick mountain woods in Martinico, and other of the Weſt-India iſlands; flowering in ſpring. Cultivated at Kew in 1794.

9. The ſheaths of the leaves, the panicle and the petals are dotted, whence the name. Native of America.

10. This alſo is a native of America.

11. Native of the Eaſt-Indies [h].

12. This is an elegant plant, a foot and half high, paraſitical on the trunks of vaſt trees, from which

[a] Long's Jam. 3. 715. [b] Linn. [c] Linn. [d] Swartz. obſ. [e] Jacquin. [f] Swartz. [g] Ibid. [h] Linn.

it hangs down towards the ground. Roots thick, fibrous, numerous. Stem ſimple, ſmooth. Leaves two, obtuſe, quite entire, ſhining, veinleſs, coriaceous, flat, alternate in two rows, half a foot long, erect like hare's ears, each ariſing from an oblong, thick, ſtriated, ſpongy body, forming the baſe of the ſtem. Spathes ſmooth, ferruginous, numerous, compreſſed below the flowers, imbricate, alternate, diſtich, covering the ſpadix, looſe and parulous in flowering time. Spike looſe, compoſed of about ten handſome white flowers, four inches in diameter, all pointing one way. Native of Martinico[a].

Cultivated at Kew in 1794.

13. Roots round, thick, filiform, whitiſh. Stem from one to two feet high, ſimple, erect, round, leafy, ſmooth. Leaves ſheathing, alternate, ſubdiſtich, from two to three inches long, oblong, entire, thickiſh, veinleſs, ſhining. Flowers terminating, two or three, ſeſſile, large, whitiſh yellow. Spathes a few, ovate, compreſſed. Petals almoſt equal, lanceolate-linear, ſpreading, the two inner narrower and white. Tube of the nectary compreſſed, gibbous, ſhorter than the petals; lip trifid, the lateral ſegments entire, the middle longer, erect, ſubulate-linear. Column incloſed within the tube of the nectary, gibbous, having at the top four pedicelled, obovate, compreſſed anthers, under a four-celled cover. Capſule oblong, attenuated at the baſe, three-cornered, three-valved, opening in the middle. Seeds reſembling ſaw-duſt[b].

Native of the mountain woods in Martinico; and in Jamaica, but not common. It ſmells very ſweet during the night.

14. Native of America. Cultivated at Kew in 1794.

15. Roots ſeveral, filiform, flexuoſe, creeping. Stem ſheathed with the rudiments of leaves. Leaves alternate, fleſhy, ſharp, a finger's length. Native of Japan[c].

16. Roots thick, numerous, filiform, ſtrict, whitiſh, knee-jointed. Stem one-leafed, thick, round, ſheathed, a foot high, thickened towards the roots, knotted. Sheaths cloſed, alternate, cloſely ſurrounding the ſtem, keeled, ſtreaked, membranaceous, whitiſh. Leaf in the middle of the ſtem ſeſſile, ſheathing, from round awl ſhaped, deeply grooved, erect, ſpotted, thick, fleſhy. Spadix from the ſinus of the baſe of the leaf, and of the ſame length with it, erect, round. Spathes minute on the ſpadix, and below the flowers; which are from twelve to fifteen. large, whitiſh, yellow, ſeſſile. Petals three outer, lanceolate-linear, long, ſpreading; two inner linear. Nectary ſomewhat funnel-ſhaped, embracing the column, erect, compreſſed, bellying at the baſe, keeled, dilated at top; lip ovate, with an awl-ſhaped, ſtriated, veined, ſpreading, whitiſh point. Column minute, incloſed within the nectary, keeled, hollowed in front, bearing at top four, oblong, bipartile, pedicelled anthers, concealed by a four-celled cover. Germ very long, round, filiform. Stigma moiſtened in front under the cavity of the anthers. Capſules an inch long, oblong, pendulous, ſix-grooved, three-valved, many-ſeeded. Seeds duſty, briſtly. Native of the Weſt-Indies, near the coaſt; flowering in ſpring[d].

17. Native of the Philippine iſlands; on trees[e].

18. Root thick, fungous, crinite, knobbed, paraſitical. Leaves ſeveral from the knob of the root, from two to three feet long, and two fingers broad, ſmooth, ſhining, browniſh green, thick. Flowering-ſtems ſeveral, undivided, round, green, ſhining. Three of the petals are narrow, oblong, of a fine red colour within, with white edges, on the outſide white and green, in ſtreaks, with a tinge of red; nectary yellow, with red lines.

Native of Malabar, on different trees[f].

19. From a matted root this ſends out ſeveral leaves three inches long, and not a quarter of an inch broad, almoſt triangular, and of a yellowiſh green colour. From the midſt of theſe comes the flowering-ſtalk. Each flower is made up of four little white petals, ſpotted with brown, and one large one with fewer ſpots, on which is a ſmall yellow hood, and oppoſite to it one like it of a blue colour; on pedicels an inch long, round the top of the ſtalk. Native of Jamaica, on the ebonies[g].

20. Native of America.

21. Native of the Eaſt-Indies.

22. Three feet in height. Root white, woody, bent in, curled, fixing itſelf into the bark of trees by its capillary hairy fibres. Stem riſing between two rows of leaves, ſimple, ſhining, ſmooth, marked with rings. The leaves which come out from the top of the ſtem, and when dry conſtitute the ſtem itſelf, are oblong-narrow, equally thick and broad on every ſide, folded together, ſmooth, ſhining, without any viſible veins or nerves. Flowering-branches ten or twelve together, riſing ſtraight from among the leaves, green, rigid; accompanied at the baſe by abundance of very minute whitiſh buds, gradually enlarging, but not opening till they have acquired a conſiderable ſize. All the flowers opening together invert the ſtem, and reſemble a fox's tail; they are on whitiſh peduncles, iſſuing from a ſmall acute bracte, ſtiff, thick, oblong, irregular, whitiſh, ſpotted with red, blue and lurid colours.

Native of Malabar, where it flowers in april and october, the flowers continuing two months, and a branch ſet in water will flower for a month[h].

23. Roots thick, like packthread. Leaves like Crinum or Squills, fleſhy, half a foot long. Stem two feet high, naked, ſurrounded by a few acute, very ſhort ſcales. Flowers ſnow-white, like thoſe of Orchis Suſannæ, the ſize of Narciſſus flowers; the two ſide petals are orbiculate, the three others are ovate: cowl three-leaved, the two ſide ones oblong, the middle haſtate, bifid, with two awl-ſhaped briſtles. Obſerved in the Eaſt-Indies by Oſbeck[i]; on branches of trees, on the coaſt of Java, alſo by Rumphius. The flowers are large, and odoriferous: lying in a room they do not wither for ſeveral days, and fill it with a moſt agreeable ſmell. On the iſle of Ternate none but princeſſes are allowed to wear this precious flower[k].

24. Roots filiform, ſtrict, whitiſh. Leaves broad-lanceolate, acuminate, keeled at the baſe, compreſſed, growing on an oblong, fleſhy, ſmooth, fibrous, ſucculent, compreſſed bulb, involved in membranaceous ſheaths. Spathe two-leaved, one leſs than the other, acuminate, at the baſe of the ſcape among the leaves. Scape from the middle of the bulb, ſolitary, round, erect, with a few minute ſpathes. Flowers terminating, four or five, large, ſubſeſſile. Petals linear, acuminate, reflex, yellowiſh. Nectary, lip heart-ſhaped, blunt, concave, dark-blood-red, ſtreaked with white at the baſe, yellow at the tip. Column three-cornered, ſpotted with red at the baſe, three-horned at the tip, bearing two pedicelled, bipartile anthers. Capſules oblong, acuminate, pendulous.

Native of the mountainous parts of Jamaica[l]. This is one of the few ſpecies yet introduced; we are obliged to Mr. Alexander Anderſon for it in 1786. It flowers here in january and february[m].

25. This is a native of America. Linnæus ſets it down as the growth of both Indies, ſuppoſing it to be the Angræcum terreſtre primum of Rumphius, which Swartz aſſures us it is not, becauſe it is drawn without leaf-bearing bulbs, and is ſaid to grow on the ground. It is probably a ſpecies of Limodorum[n]. Loureiro has deſcribed a plant cultivated in the gardens of China and Cochinchina, as the E. tuberoſum of Linneus; but as he refers to Rumphius, and ſays that it is not paraſitical on trees, but grows on the ground, it may alſo be a Limodorum, or at leaſt is a different ſpecies from this.

26. Root fibrous. Plant little more than an inch high.

[a] Jacquin. [b] Swartz. [c] Thunberg.
[d] Swartz. [e] Act. upſ. [f] Hort. malab.
[g] Sloane. [h] Hort. malab. [i] Linn. ſpec.
[k] Oſbeck. [l] Swartz. [m] Hort. kew.
[n] Swartz. obſ.

high. Leaves diſpoſed like thoſe of Iris, even, acute, all radical. Scapes between each of the leaves ſolitary, the length of the leaves, with three or four minute leaflets ſcattered over them. Flowers terminating one or two, from a three-valved glume; the three upper petals ſpreading, oblong, the uppermoſt very ſmall; the two inner toothed: lip trifid, the ſide-lobes ſubcordate, the middle larger, bifid.—Or, according to Allamand, in mantiſſa—petals ovate-oblong, acute; upper lip of the nectary ampullaceous-tabular, emarginate, lower very large, ſinuate with four lobes on each ſide, oppoſite, equal. Capſule ſpherical, ſix-keeled.

Obſerved in Surinam by Dahlberg[b].

27. Root perennial, conſiſting of a few thick fleſhy fibres. Leaves radical, ſeveral, equitant, erect, clothed with ſome brown permanent ſcales at the baſe, rigid, rather ſharp-pointed, with a rough margin towards the top, channelled, nerved, ſmooth on both ſides, when dry becoming longitudinally ſtriated. Stalk growing on the outſide of the leaves, and not quite ſo long, erect, ſimple, brown, bearing from four to ſix flowers, and furniſhed with three or four alternate, ſheathing, acute, ſtriated, brown ſcales, and compreſſed towards the top. Flowers alternate, ſeſſile, a little drooping. Bractes ſolitary, reſembling the ſcales on the ſtalk, but ſmaller. Petals obtuſe, ſmooth, pale green marked with red longitudinal ſtreaks; three external and ſpreading, two internal, approaching each other, and a little ſhorter. Lip of the nectary as long as the inner petals, blunted, keeled underneath at the baſe, erect and ſomewhat criſped in the margins, marked on the upper ſide with two tubercles, which meet together and cover a longitudinal furrow, in front it is of a broad lanceolate figure, obtuſe, pale yellow elegantly ſpeckled with purple. Column of the fructification ſeparate from the nectary, and half the length of its lip, curved, hollowed beneath, and ſpotted with red, obtuſely keeled and reddiſh on the back, ſlightly three-cleft at the tip. Cover roundiſh, ſwelling, yellow, fixed by its baſe to the column, looſe above, hollowed behind. Anthers obſcurely two-lobed, yellow, pellucid. Stigma depreſſed. Germ an inch long, roundiſh, incurved, ſtriated, green. The flowers have a ſweet lemon-like odour, pungent, but not ſtrong, moſt remarkable at night or on entering the hot-houſe in a morning. On account of this perfume, the plant is much cultivated in China[c].

Thunberg makes it a Limodorum, and Swartz thinks that it ſhould rather be referred to that genus, as ſeveral other ſpecies may probably be. Thunberg however afterwards referred it to this genus.

Loureiro remarks, that the nectary is not turbinate in this and his tuberoſum, and that there are ſeveral varieties, particularly with flowers of a pure white, much eſteemed for its very ſweet and delicate ſmell.

Native of China and Japan. Cultivated by the Marchioneſs of Rockingham[d], before 1792.

28. Flowers white. Common on walls and in hedges in Japan. Paraſitical.—Chevalier Thunberg, in his travels through Japan, obſerved it at Miſima, tied up in bundles, and hung out before a houſe. It can live ſeveral years without water or other nouriſhment, and yet grow and flower all the while[e].

29. Native of America. Swartz affirms, that the E. ophioglooſſoides of Jacquin is the ſame with his trigonoflorum. See n. 75. Dombey's ſpecimens, brought from Peru agree with Plumier's figure.

30. Roots numerous, filiform, rigid, whitiſh. Stems aggregate, often united at the baſe, filiform, a foot high, erect, ſheathed, ſmooth. Leaf terminating, ovate-lanceolate, half the length of the plant, acuminate, entire, keeled, channelled at the baſe, compreſſed, ſmooth, thick, veined. Sheaths of the ſtem long, acuminate, ſtreaked, withering. Peduncles ſhort, two-flowered. Common ſpathe ovate, acuminate, compreſſed, gaping, emitting pedunculs that are bent down, with nodding flowers; of a pale green colour. Corollas ſmall, acuminate, four-petalled: the two outer petals, which are the upper and lower, oppoſite, lanceolate, acute, patulous; the two inner lateral, linear, ſhorter, erect. Nectary of the ſame ſhape with the inner petals, but leſs, erect, channelled, pale; lip obtuſe, recurved. Column of the fructification round; at the top, in a hollow, two roundiſh anthers, covered with a two-celled lid. Capſules ovate, ſmall, acuminate, ſix-grooved, three-valved.

Native of the high mountains of Jamaica, on the trunks of old trees[f]; and in the thick woods of Martinico[g]. Cultivated at Kew in 1794.

31. Native of America.

32. Found at the Cape of Good Hope by Thunberg, paraſitical on the trunks of trees[h].

33. Stems ſeveral, a little divaricated, compreſſed, entirely clothed with leaves; which are alternate, ſheathing, embracing, of a long oval form, obtuſe, entire, ſomewhat reflexed at the tip of the margin, obſoletely nerved, coriaceous, ſmooth on both ſides, dark green above, purple beneath. Flower-ſtalk erect, very long, ſimple, compreſſed, with many knotty joints, ſmooth, green, but entirely covered with brown membranaceous ſheathing ſcales, which are alternate, ſharpiſh, compreſſed, keeled and ribbed. Spike terminating, erect, forming a globoſe denſe head of many flowers. Bractes, ſolitary under each flower, lanceolate, concave, acute, purpliſh green, one third the length of the germ. Flowers pale greeniſh purple, with a faint herbaceous ſmell. Petals ſpreading, of equal length, the innermoſt narroweſt, lower ones ſomewhat ſickle-ſhaped, pointed upwards. Lip of the nectary a little longer than the petals, concave, keeled, ſlightly five-lobed; the lateral lobes largeſt and roundiſh, the odd one very ſmall, ſhorter than the reſt, and appearing like a little tubercle. Column of fructification bent down, affixed to the lip, and but half as long, triangular with the angles purple, terminated in front by two lateral yellow cloſed lips, at the top abruptly truncated. Cover of the anthers roundiſh, flattened, yellow, fixed by its baſe to the above-mentioned lips, looſe in the upper part, cloſing the hollow truncated top of the column. Stamens placed in the cavity of the column behind the cover. Filaments very ſhort; anthers in pairs, yellow, pellucid. Germ ſlender, rather cylindrical than angulated, a little twiſted.

This approaches to E. ſecundum; from which it differs in having a column ſhorter than the petals, capitate and purpliſh or browniſh-green flowers, inſtead of violet ones, leaning all one way. The ſtructure of its flowers ſeems like thoſe of E. anceps of Jacquin; but in the latter the ſpike is lateral, and its flower-ſtalk much ſhorter than in our plant.

Native of Jamaica. Cultivated by the Hon. Mrs. Barrington, at Mongewell in 1791[i].

34. Root of a few thick fleſhy long and nearly ſimple fibres, ſlightly downy. Bulbs above ground, numerous, ovate, but little compreſſed, ſmooth, green, ſomewhat glaucous, an inch long. Leaves ſheathing, a little ſpreading, pointed, entire, nerved, very ſmooth, paler beneath; moſt numerous from the radical bulbs, clothed with oblong acute concave ſheathing ſcales; fewer from the ſummits of the bulbs. Stalks thrice as high as the bulbs, erect, thickly covered at the baſe with ſmaller, concave, bluntiſh, reddiſh ſcales, imbricated in a two-fold order; in the upper part roundiſh, ending in a ſimple cluſter of many flowers. Flowers on foot-ſtalks, ſpreading, white, without ſmell. Pedicels angular, ſhorter than the germ. Bractes ſolitary, linear-lanceolate, acute, membranaceous, nearly equal to the flowers, withering. Petals nearly equal, a little ſpreading, ovate, bluntiſh, concave, white

[b] Linn. ſpec. & mant. [c] Smith ſpicil. [d] Ibid. [e] Thunb. jap. & trav. [f] Swartz. [g] Jacquin. [h] Linn. ſuppl. [i] Smith ſpicil.

and

and ſemipellucid. Lip of the nectary of the ſame colour and nearly the ſame form with the petals, except its having on each ſide a ſlight angle, which ſeems bent upwards. Columns of the fructification very obtuſe, pitcher-ſhaped, notched at the top, without any cover. Anthers on the ſummit two, ſeſſile, ſmall and yelloviſh. Stigma a tranſverſe chink, not very evident, under the anthers. Germ oblong, with three membranous pointed wings, between each pair of which, on the ſides of the germ, are two ſmall intermediate wings.

Native of Jamaica. It flowered in the garden of the Hon. Mrs. Barrington in february 1793: alſo in Kew garden about 1791 [s].

35. Root of numerous branched fleſhy fibres, brown downy and divaricating. Bulbs ſeveral, above the ſurface, large, ovate, ſlightly compreſſed, ſmooth, green, with an unequal and ſomewhat furrowed ſurface. Leaves three or four from the top of each bulb, ſheathing, a little ſpreading, pointed, entire, ſmooth, dark green, not very rigid, waved in the margin. Flower-ſtalks three inches high, nearly erect, bearing one flower, rarely two, round, green, ſmooth; clothed with four or more ſheathing alternate ſcales, which are ovate, concave, green with a ruſty-coloured powdery down. Flower from the uppermoſt ſcale, a little drooping, about the ſize of Limodorum Tankervilliæ, inodorous. Petals lanceolate, obtuſe, ſomewhat ſucculent, ſlightly ſpreading, greeniſh towards the tips, of an olive brown: the two innermoſt rather the ſmalleſt; the two lowermoſt lengthened out at the baſe, and united into a ſhort blunt pouch. Lip of the nectary ariſing from the back part of the inſide of this pouch, unconnected with every thing above, ſomewhat ſhorter than the petals, covered on its upper ſide with an oblong yelloviſh deeply furrowed caloſity, inverſely heart-ſhaped in front; its margin is three-lobed, the lateral lobes ſmall, acute, entire, erect, thin and tranſparent, terminating one very large, of a ruſty brown, blunt, hollowed above, ſwelling below, pale and beautifully fringed all round the margin. Column of the fructification white, elongated at the baſe, connected by its back to the pouch of the corolla, and by its fore part at the bottom of the lip of the nectary; incurved and blunt at the top; behind obtuſely keeled; flat and with two ſlight furrows before. Cover pointed, obſcurely three-celled within. Stamens red, cloſe together. Anthers two on each filament, obovate, yellow. Stigma large, very much excavated. Germ ſomewhat longer than the pouch of the flower, green, nearly cylindrical, with ſix furrows.

This is the moſt diſtinguiſhed of the ſpecies hitherto introduced among us, not only on account of its ſize, but its ſingularity. Neither this nor the preceding occurred to Dr. Swartz, who inveſtigated the iſland of Jamaica with no leſs ardour than accuracy. It is to be hoped therefore that more new ſpecies may hereafter be diſcovered there.

Native of Jamaica. It flowered in april 1791, in the collection of the Hon. Mrs. Barrington; and in Chelſea garden in the year following [t].

36. to 84. All theſe ſpecies were obſerved by the indefatigable Swartz in the Weſt India Iſlands, chiefly in Jamaica. Moſt of them are new, but ſome had been found before by Profeſſor Jacquin; and five by Sloane, Browne, *&c.*

36. This plant hangs down from the branches of trees and creeps up others to forty feet high. Stem jointed at the diſtance of about five inches, and at every joint fibres three or four inches long, catching hold by their broad viſcid end of any part of a tree they come near; it is about three quarters of an inch in diameter, very ſmooth, round and deep green, ſolid, juicy, and ſometimes branched: here and there, oppoſite to the tendril, comes out a thin membranaceous leaf, from a broad beginning ending in a point.

Native of Jamaica [u], and Hiſpaniola [x].

[s] Smith ras. [t] Ibid. [u] Sloane. [x] Swartz.

37. Plant a foot and a half high, leafy, paraſitical. Roots fibrous. Branches compreſſed a little, ſmooth, aſh-coloured. Leaves oblong, obtuſe, coriaceous, rigid, veinleſs, entire, ſhining, ſheathing at the baſe, dirty green, alternate, an inch and half long. Spathes cordate-ovate, acute, converging. Spikes looſe, diſtich, an inch and half long, four-flowered or thereabouts. Flowers ſmall, inelegant, greeniſh; petals ſomewhat rigid, equal in length, the three outer lanceolate, the two inner linear. Lower lip of the nectary oblong-cordate, acuminate, concave, rigid, the length of the petals, of which it occupies the place of the third interior one. Anthers roundiſh. Germ a little longer than the corolla. The reſt as in E. lineare.

Native of Martinico [y], and Jamaica.

38. Native of Jamaica [z]. Cultivated at Kew in 1794.

39. Swartz thinks it probable that his umbellatum may be the ſame with the diſforme of Jacquin, which he thus deſcribes.

Paraſitical, ſmooth, ſeldom a foot in height. Roots round, fibrous, aſh-coloured, numerous. Stems round, leafy, commonly horizontal or pendulous. Leaves oblong, coriaceous, pale green, ſheathing, clothing the whole ſtem, alternate, an inch or an inch and half in length, moſtly diſform. Spadix very ſhort, concealed within the ſinus of the terminating leaf, five-flowered or thereabouts. Spathes very few. Flowers ſomewhat fetid, greeniſh white, rigid.

Common in the vaſt woods of Martinico [a], and in Jamaica.

40. Native of Jamaica. The anceps of Jacquin is probably a variety of E. ſecundum, n. 7 [b].

41. Paraſitical, a foot high. Roots fibrous, aſh-coloured, round, numerous. Stems ſimple, round, leafy, ending in a very looſe, diſtich ſpike, four-flowered or thereabouts. Leaves coriaceous, rigid, ſhining. Spathes very large, coriaceous, rigid, almoſt the length of the flowers, which are inelegant, ſmall, rigid and thick: petals ſpreading very much, the three outer ovate, the two inner lanceolate and a little ſhorter. Lower lip of the nectary cordate-roundiſh, blunt with a ſmall point, flat, upright, the length of the petals, with a toothlet on each ſide at the baſe. Anthers ſimple. Germ oblong, incurved, three-cornered. The reſt as in E. lineare.

Native of woods in Martinico [c], and Jamaica.

42. to 45. Natives of Jamaica [d]. Of theſe and others we lament that we have not deſcriptions from the accurate hand of Swartz.

46. Roots fibrous, round, aſh-coloured, numerous, paraſitical. Stems ceſpitoſe, quite ſimple, two or three inches high, round, ſmooth, leafy, ending in a ſpadix bearing one flower, ſeldom two, very ſeldom three: whence there are very few ſpathes. Leaves awl-ſhaped, acute, ſmooth, ſhining, ſomewhat rigid, ſeſſile, alternate, an inch long. Flowers ſmall, ſcarcely coloured, erect, of the ſame ſtructure with E. lineare, except that the germ is twice as long as the petals. Capſule ſix-grooved, the ſize of a ſmall pea.

Native of the woods of Martinico [e], and Jamaica [f].

47, 48. Natives of Jamaica [g].

49. Paraſitical and the largeſt of its ſort. Roots large. Leaves many, long, narrow, ſmooth, dark green, ſomewhat like thoſe of our common white Lily. Stalk round, tough, brown, crooked, ſix feet high, with joints at every eight or nine inches diſtance, where are branches ſtanding ſtraight out, with ſeveral flowers on peduncles an inch long. Petals ferruginous ſpotted [h].

Jacquin refers Sloane's plant here deſcribed to his altiſſimum. Swartz thinks that the carthagenenſe of Jacquin may poſſibly be the ſame with his undulatum. Jacquin thus deſcribes it.

[y] Jacquin. [z] Swartz. [a] Jacquin. [b] Swartz. [c] Jacquin. [d] Swartz. [e] Jacquin. [f] Swartz and Jacquin. [g] Swartz. [h] Sloane.

Paraſitical,

Paraſitical, with the habit of Aletris guineenſis. Roots round, whitiſh. Leaves radical, lanceolate-oblong, acute at both ends, quite entire, ſmooth, coriaceous, green on both ſides and variegated with black dots, a foot long, two inches wide, few. Scape round, ſlender, browniſh red, a foot and half high, racemed at the top. Peduncles an inch long, alternate, an inch and half diſtant from each other, the upper ones one-flowered, the loweſt five-flowered. Spathes lanceolate, membranaceous, very ſlender and ſhort at the joints, and ſubaxillary at the peduncles and flowers; theſe are handſome, with whitiſh petals ſpotted with ferruginous purple; upper lip of the nectary pale purple, lower of the ſame colour with the petals, with a violet-coloured diſk. Anthers orange. Fruit an inch and half long[a].

Jacquin's plant is a native of Carthagena, in thick woods; that of Swartz, Sloane, and Browne, of Jamaica.

50. Swartz ſuſpects that his variegatum may be the ſame with the tetrapetalum of Jacquin, who deſcribes it thus.—It is an elegant paraſitical plant. Roots round, aſh-coloured, fibrous. Leaves radical, awl-ſhaped, acuminate, keeled, ſomewhat rigid, coriaceous, obtuſely angular on the back, with acute-angular margins, pale green, ſometimes rugged with ruſt-coloured dots, ſometimes without and quite ſmooth, from an inch and half to ſix inches in length. Scape round, ſlender, from a foot to two feet in length. Spathes lanceolate, ſmall, at the joints and peduncles. Peduncles about ten, one-flowered, forming a handſome raceme pointing one way. Flowers ſweet-ſmelling, elegantly variegated with purple, violet, yellow and red. Petals four, obovate-acuminate, unequal, ſpreading much, the lower bifid at the tip, the other three repand, of which the uppermoſt is a little ſhorter than the reſt. Diſk of the nectary oblong with a cruciform bump. The lateral ſegments of the lower lip obovate and obtuſe. The reſt as in E. carthagenenſe.

Native of the woods in Jamaica[b], and Hiſpaniola[c].

51. Native of Jamaica and Hiſpaniola.

52. to 55. Natives of Jamaica.

56. Native of Hiſpaniola.

57. to 61. Natives of Jamaica[d]. Of all theſe we have no deſcription.

62. This is an elegant paraſitical plant. Roots round, fibrous, aſh-coloured, numerous. Leaves acute, enſiform-oblong, veinleſs, ſhining, quite entire, thickiſh, an inch wide, and half a foot long, keeled at the baſe, in other parts flat, each ſpringing from a joint, or an ovate, compreſſed, ſmooth tuber, ſometimes as big as a gooſe's egg, which is placed on the baſe of another root-leaf or two, like the others. Between this and the joint ariſes a ſolitary, round, ſmooth ſcape, of a ruſt-colour, ſlender, inclined, four feet high, racemed at top, clothed at the peduncles and joints with membranaceous, lanceolate, aſh-coloured ſpathes. Peduncles two or three-flowered, alternate in two rows. Flowers without ſcent, yellow with brown ſpots, numerous. Petals oblong, diſtinct, acute at both ends, waved, nearly equal. The middle ſegment of the lower lip of the nectary is ſquariſh, and the whole is yellow without ſpots. The reſt as in E. carthagenenſe.

Native of the woods of Martinico[e]. Cultivated at Kew in 1794.

Jacquin mentions another, which he names E. violaceum, from its beautiful violet-coloured flowers. He found it on a very tall arboreous Cereus, and had not an opportunity of examining it particularly; it appeared to him to have the habit of the ſpecies thus deſcribed.

63. Native of Jamaica. Introduced here in 1786, by Hinton Eaſt, Eſq. It flowers in October[f].

64. This has many white thick fibres like thoſe of Leeks, or the tendrils of Ivy, taking firm hold of the bark of trees, and matted together; theſe ſend up one thick greeniſh roundiſh compreſſed bulbous or tuberous leaf, of an inch diameter, covered with ſome brown withered filaments. From the top of this come two ſmooth ſtriated hollow hard pale green leaves, three inches long and one inch broad, between which ſprings out a naked brown jointed round ſmooth ſtalk, about a foot high, near the top of which ſtand ſeveral long reddiſh purple flowers, very beautiful.

Native of Jamaica, on the Ebonies and other trees in the Savanna woods, plentifully[g]. Cultivated at Kew in 1791.

65. Native of Hiſpaniola.

66. to 69. Natives of Jamaica[h].

70. Roots ſmall, branched, fibrous. Stems pendant, ſimple. Leaves alternate, numerous, ſmall, reflex, quite entire, ſubtomentoſe, ſtem-claſping. From the axils of the leaves flowers ſolitary, on very ſhort peduncles. Corolla of a coral red colour, the upper and the two lower petals of the ſame ſize and figure; the two lateral ones larger and wider; nectary ſmall, three-lobed, the two upper lobes rounded and concave, the lower emarginate. Capſule red, ovate, warted.

Native of Guiana, on the trunks of old trees which are ſometimes quite covered with it.

71. to 74. Natives of Jamaica[k].

75. This little paraſitical plant is only about four inches high. Roots fibrous, whitiſh, numerous. Leaf cauline, acute, quite entire, coriaceous, rigid, veinleſs, flat, ſhining, two or three inches long. From the ſinus of this come out ſucceſſively three or four ſpadixes, racemed, ſimple, ſlender, erect, a little longer than the leaf, having about ten flowers, and clothed at the baſe with a few ſpathes, and ſmall floral ones. Flowers ſmall, directed all to the ſame ſide, without ſcent, on ſhort peduncles, of a dirty yellow colour.

Native of the mountain woods in Martinico[l], and Jamaica[m].—According to Swartz, Jacquin's ophioglooſſoides is not that of Linnæus, but this ſpecies.

76. Native of Jamaica.

77. Native of Hiſpaniola.

78. to 83. Natives of Jamaica.

84. Native of Hiſpaniola[n].

Of all theſe ſpecies we expect deſcriptions from the accurate hand of Dr. Swartz, the firſt diſcoverer of them.

85. Paraſitical, a foot high. Roots fibrous, whitiſh, thick, round, long. Leaves radical, two, three, or four, lanceolate, acute, coriaceous, flat, ſtiffiſh, quite entire. Scape ſimple, compreſſed, erect, ten-flowered or thereabouts. Common peduncles few, lateral, few-flowered. Flowers ſmall, ſeſſile.

Native of Martinico.

86. Paraſitical. Roots round, fibrous, numerous. Leaf round, acute, ſlightly grooved within, ſmooth, fleſhy, at bottom a finger in thickneſs, in length from one to two feet, but ſometimes four feet, ending at the baſe in a knot or roundiſh tubercle, permanent after the leaf is decayed. Scape round, two feet long or more. Spathe lanceolate. Peduncles many-flowered. The natives call it *Cebelletas* (Cibouls or little bulbs), and make uſe of the tubercles triturated with ſalt in violent contuſions, fractures, *&c.* The whole plant is void of ſmell.

Native of Carthagena in woods, eſpecially on the coaſt[o].

Theſe two plants are not mentioned in the Syſtema vegetabilium, or in any other book that I have ſeen.

87. to 109. Theſe twenty three ſpecies are natives of the Eaſt Indies, where they were diſcovered by Koenig, and are deſcribed by him at great length, as may be ſeen in the ſixth faſciculus of Retzius's obſervations. Moſt of the ſpecies are new ones, not mentioned by any other author. A few of them

[a] Jacquin. [b] Ibid. [c] Swartz. [d] Ibid. [e] Jacquin. [f] Hort. kew. [g] Sloane. [h] Swartz. [i] Aublet. [k] Swartz. [l] Jacquin. [m] Swartz. [n] Ibid. [o] Jacquin.

however are probably deſcribed and figured by Rumphius. Neither Koenig nor Retzius have given any diagnoſes or ſpecific characters; inſtead of theſe I have ſubſtituted for the preſent the deſcriptions of the leaves.

87. Peduncles axillary, almoſt erect, ſometimes pendulous, round, ſmooth, jointed, woody at the joints bracted undivided half way, a foot and half long, within the raceme angular. Pedicels ſpreading very much, ſcattered, bracted at the baſe, round, ſmooth, white, the length of the flowers. Bractes oblong, preſſed cloſe, acute, ruſt-coloured. Petals united at the baſe to the nectary, flat; two lateral, ſpreading very much, ovate, broad, acute, larger; three inferior obovate, the middle one largeſt; all ſnow-white with a large roſe-coloured ſpot at the end. Nectary inflated, rounded, three-parted, aſcending, horned in the upper part, recurved, much larger than the corolla: ſegments of the inferior or inflated apex lateral, obliquely ovate, toothed at the edge, larger, ſnow-white; the upper linear, narrow, two-toothed and incurved at the tip, coloured, roſe-purple, ſomewhat more rigid; the lower divided horizontally to the middle: the lower part of the nectary in front is an erect truncated body, rounded on the outer ſide, concave on the inner, with a large hollow filled with a whitiſh honey juice; at the apex is a heart-ſhaped ſcale, concave, keeled, reſembling the head of a fowl, below this are two large globular yellow anthers, adhering to the truncated body, ſo glutinous that they may be drawn out into threads, divided on the outer ſide by a gaping chink. Style none: the ſtigma two approximating ſcalelets, below the tip of the ſcale and covering the anthers, faſtened to the truncated body of the nectary, ſilky-ſubtomentoſe, and very ſmall. Silique club-ſhaped triangular, the angles acute, attenuated at the baſe, truncated at top, thick, crowned with the withering corolla, ſmooth and more than an inch in length.

88. Swartz has given the ſame name to an American ſpecies: ſee n. 50.

Roots of the former year, bulbs above ground, erect, oblong, narrow, compreſſed a little, clothed with four or more alternate membranaceous ſcales, an inch long, ſcarcely three lines broad, green, putting out below horizontal filiform flexuoſe whitiſh fibres. Root of the preſent year coming out laterally from the baſe of the former, ſcarcely bulbous, covered by three oblong acute ſheaths, ſpreading, membranaceous and purple at top. Stem none. Leaves in threes, variegated with green and blood red, with the edges white and red. Scape erect, a palm high, ſolitary, (ſeldom two) angular, ſtriated, ſmooth, coloured, terminated by an oblong raceme. Peduncles ſimple, ſubalternate, ſpreading very much, roundiſh, club-ſhaped, ſtriated, coloured, ſcarcely the length of the flowers. Spathes or bractes ſolitary, faſtened below the peduncles, pendulous, preſſed to the ſcape, linear-acute, ſmooth, membranaceous, of a ſort of roſe colour, the length of the peduncles. Petals ſpreading very much, oblong, acute, the edges rolled back, membranaceous, roſe-coloured, the two lateral inferior ones ſomewhat narrower, the two upper ones and the loweſt equal. Nectary margined; margin flat, the upper broader, toothletted, divided at bottom, ſegments diſtant, lanceolate, acute, membranaceous, lemon-coloured. Inner part vaulted, covering the proper turbinated nectary or truncated body, over which is a heart-ſhaped, appreſſed, white ſcalelet, convex on the outſide, and within having two cells incloſing the anthers, which are ſeſſile, faſtened to the truncated body, oblong, divided by a little groove, yellow. Silique club-ſhaped, compreſſed a little angular with deeper grooves

89. Roots capillaceous numerous flexuoſe whitiſh. Stems many crowded roundiſh flexuoſe jointed perennial ſcarcely a ſpan high. Racemes terminating ſimple. Flowers remote. Sheaths two or more, oblong, membranaceous, white and roſe-coloured mixed. Petals four; loweſt navicular, large, deſcending apex horned and a little blunt, aſcending broad, three-parted, the middle ſegment lanceolate, narrower, the ſide ones broader; upper petal inſerted in the horned apex, erect, a little incurved, club-ſhaped, flat, emarginate and a little criſped at the top, white, the length of the lower one; two petals within the ſegment of the lower petal at the baſe of the nectary, aſcending a little, lanceolate, equal in length to the ſegments of the lower petal, whitiſh. Nectary a truncated body, ſemicylindric, ſhort, having a large hollow in the fore part, rounded behind, and a rim running to the horn on each ſide; hollowed at top with an orbicular convex ſcalelet, divided by a longitudinal partition into two cells for the anthers, the whole ſnow-white. Filaments very ſhort and ſlender. Anthers ſubglobular with a little groove, large.

90. Roots capillaceous, flexuoſe, white, paraſitical. Stems ſeveral, round, naked a little way above the root, the reſt covered with oblong, tubular, acute, ſtriated, rigid, whitiſh ſcales. Leaves quite entire, rather fleſhy, ſcarcely the ſize of Hypericum leaves, but narrower. Racemes ſmall, axillary, peduncled, reflex, ſcattered, frequent towards the top, few next the root, ſhorter than the leaves. Peduncles axillary, ſimple, ſolitary, round, ſheathed: ſheaths oblong, acute, ſhort. Spathe one-leafed, at the baſe of the germ, faſtened to the peduncle, ovate, acute, recurved, preſſed to the peduncle, membranaceous, ſmooth, ſcarcely the length of the germ. Upper petal on the corolla erect, ovate-lanceolate, acute, a little concave, whitiſh; ſecond and third faſtened to the ſide of the nectary, erect, lanceolate, a little leſs than the former; the fourth horned at the baſe in front, the horn round and inflated, aſcending towards the ſuperior petal and two-parted, the ſegments ſpreading in two rows, recurved at the tip, ovate, acute, ſhorter than the flower; the fifth faſtened to the inſide of the horn of the fourth, oblong-club-ſhaped, riſing to an obtuſe apex, a little recurved, with a very ſmall toothlet in the middle, a little ſhorter than the ſegments of the fourth petal. Nectary a truncated erect body, a little compreſſed, terminated by double ſcalelets, which are erect, one at the back of the nectary, the other in the tranſverſe partition, faſtened above the truncated diſk, cordate-acute. Filaments ſcarcely any. Anthers fix, club-ſhaped, yellow, ſubpellucid, three in each cell. Silique club-ſhaped, angular, grooved, a little incurved, the ſize of a grain of Rie, or hardly leſs than a grain of Wheat. The whole plant is ſcarcely a foot high, the leaves are ſmooth, and the flowers are white.

91. Roots fibrous, filiform, hirſute, white, fixed in the ground. Scape erect, clothed with ſheaths and leaves round, grooved, acute, red, with recurved linear-acute ſmooth green long ſtipules ſcattered over it, a foot high or more. Sheaths ovate acute quite entire keeled nerved membranaceous, the lower ones broader, ſhorter, greeniſh with red nerves. Spike erect cylindrical, cloſely ſet with blood-red flowers, a palm and half in length, the thickneſs of the middle finger. Peduncles very ſhort, ſingle, ending in erect germs, a little recurved at the tip, club-ſhaped, ſtriated, coloured, with keeled criſp and toothletted ſtreaks. Spathe one-leafed, faſtened to the ſcape below the peduncle, recurved and preſſed cloſe, linear acute, quite entire, ſmooth, narrow, twice as long as the flower, a little coloured. Petals irregular, the three lower ſpreading, curved towards the anterior ones, linear, acute, rolled back on the edges, ſmooth on both ſides, a little broader than the intermediate ones; the two upper petals faſtened to the germ, and with the former curved towards the anterior part, obliquely ovate, convex at the baſe, flat behind, ſpreading a little, a little ſhorter than the former. Nectary a truncated body at the baſe of the back, lobed; lobe aſcending obcordate; from the ſinus of the heart proceeds a horned body half ſurrounding the truncated body, double its length, fleſhy and of the ſame colour. Proper nectary erect, cylindric ſomewhat compreſſed,

compreſſed, ſmooth, obliquely truncated: the diſk or apex hollowed. Scalelet faſtened to the anterior margin, which is ſingular; it is orbicular, ſmooth, whitiſh, membranaceous, concave within. The two anthers are obovate or club-ſhaped, yellow, ſubpellucid, connate at the baſe, very ſmall and much reſembling thoſe of the Contortæ. Style none, except the nectary, at the back of which, a little below the diſk, is an oblong labiate cleft, the lip membranaceous and white. Silique obovate, angular, rugged, larger than a grain of Barley, crowned by the permanent apex of the nectary.

92. This is ſuppoſed to be *Herba Supplex minima* of Rumphius. It grows on trees by capillaceous fibres, a little compreſſed. Stem none. Leaves from five to ſeven, the length of the little finger. Spikes terminating, naked at the baſe, filiform, longer than the leaves, ſcarlet. Scape below the flowers round ſmooth, with a few bractes, among the flowers marked with prominent ſtreaks. Spathe ſolitary, faſtened to the ſpadix below the germ, almoſt erect, lanceolate, acute, ſmooth, membranaceous, longer than the germ, a little coloured. Petals ſix, three outer ſpreading, linear-lanceolate, ſmooth, ſemipellucid, leſs coloured, two anterior and one poſterior, two interior lying over the two anterior ones, a little broader, more concave and coloured; the ſixth poſterior erect, at the baſe broad and concave. Nectary truncated, half ſurrounding, ending above in an obcordate lobe. The truncated body is very ſhort and ſmall, covered by a white ſcalelet, containing two very minute glandular anthers. Stigma, a very ſmall oval aperture at the back of the truncated body below the tip of the diſk. Silique globular, crowned with the truncated body, having grooves with acute three-valved edges.

93. Paraſitical, by means of filiform branched ſmooth green fibres. Stems ſimple pendulous jointed leafy flexuoſe ſheathed thicker than the roots, two feet long or rather more and a little more ſlender at the baſe. Leaves ſcarcely a palm and half in length and an inch in breadth, bright green. Sheaths tubular ſmooth naked, quite entire at the mouth, the length of the interſtices, ſcarcely an inch in length, coriaceous. Flowers above the leaves, uſually ſolitary, but ſometimes ſeveral, ſpreading, ſeſſile, the ſize of thoſe in Orchis pyramidalis. Spathes heart-ſhaped, ſmall, ſomewhat fleſhy, yellowiſh, caducous. Petals lanceolate, yellow with large darker ſpots; the two upper ones aſcending, the middle one ſpreading from the lower petals, the two lateral ones larger, more reflexed towards the back, narrower, all concavo-convex. Nectary in the diſk of the flower, two-parted; upper lip ſpreading, haſtate, the upper lip recurved, and between the lower ſegments two glands connate above, below running to the other ſide, purple-roſe-coloured, horned behind, the horn ſcarcely deſcending, conical, ſharpiſh, white, half the length of the germ. Filament ſingle, faſtened within the apex of the lip, flatiſh, white, incumbent and equal to it in length. Anther, two globules divided by a groove; in the cavity of the truncated body, lemon-coloured. Style none. Stigma a cavity below the lip and diſk of the truncated body. The decurrent margins within the haſtate lip form an orifice in the horn, and are ſomewhat fleſhy, rigid and coloured, uſually roſe-colour or purple. Silique linear, three-ſided with the angles winged, incurved, aſcending ſtiffly, longer than an inch. It ſhould be remarked, that when the plant is pendulous, the parts above deſcribed are reverſed.

94. Root capillaceous few white paraſitical ſhoots in bundles preſſed cloſe to the bark, little branched, ſometimes jointed, unequal, a ſpan long, hoary, green. Racemes half an inch long, green ruſt colour. Spathes heart-ſhaped, ſolitary, alternate, ſeſſile, acute, fleſhy, ſmall, permanent, from five to eight. Flowers alternate ſpreading. Petals faſtened to the nectary, erect, linear-lanceolate, acute, a little longer than the nectary, equal, yellow. Nectary truncated at the baſe, ſemicylindric, horned on the upper ſide at the baſe: horn aſcending, ovate, inflated, ſomewhat compreſſed, a little longer than the trunkated body; in the diſk a pedicelled, concave, two-celled, roſe-coloured ſcalelet, membranaceous in front, acute, white, beaked, very ſmall. Silique round, incurved, ſmooth, ſcarcely an inch long.

95. Roots filiform very long whitiſh green paraſitical. Stem with the long roots commonly pendulous, roundiſh, ſheathed with leaves, ſimple, ſhort. Leaves ſcarcely a ſpan in length. Spikes oppoſite to the leaves, peduncled, ſpreading, flat, ſerrate, the length of the leaves, rather remote. Spathes biſarous, alternate, boat-ſhaped, compreſſed, acute, fleſhy, rigid, permanent, forming a ſerrate ſpike, one to each flower. Petals linear-acute, pendulous ſmooth, narrow, yellow. Helmet of the nectary ſcarlet, incumbent, inflated, with two lobes ſpreading a little, having an almoſt erect horn at the top, and below the horn on the inner ſurface, a tongue-ſhaped, retuſe, ſmall, aſcending lobe, faſtened to the diſk: the truncated body ſemicylindric with a concave tip, white, membranaceous, oblong, obtuſe, incloſed. Anthers ſolitary, oblong, obtuſe, grooved, large, white.

96. Roots filiform, white, paraſitical. Stems at the threads of the roots pendulous, round, ſheathed with leaves, ſhort. Leaves bright green. Spikes ſhort, oppoſite to the leaves, ſpreading very much, peduncled, club-ſhaped. Peduncles roundiſh, ſmooth with a few coloured dots, woody, ſcarcely the length of the leaves; bractes ſolitary, preſſed cloſe, heart-ſhaped, ſmooth, rigid, towards the middle of it. Spathes ſeveral, alternate, ſomewhat ſpreading, heart-ſhaped, acute, compreſſed at the back, ſmooth, coriaceous, one to each flower. Corolla ſix-petalled, or more properly one-petalled; five ſegments ſpreading, linear-lanceolate, nearly equal, yellow, long; the ſixth galeate, inflated, incumbent on the nectary, horned at the tip; horn erect, oblong, rounded, bearded, white, the reſt orange-coloured. Nectary truncated, erect, concave, ovate at the tip, ſubmembranaceous, white, covered with an oblong obtuſe concave white, membrane, containing a ſolitary yellowiſh anther. Style club-ſhaped, ſmall, within the hollow of the nectary, in ſome ſpecimens. Silique filiform, ſtriated, with a groove on each ſide, ſmooth, longer than a palm, and one line in diameter.

97. Roots filiform ſmooth white paraſitical. Stems ſimple erect round ſmooth ſheathed ſhort. Leaves a ſpan long. Peduncles next the roots, alternate, ſpreading very much, round, ſmooth towards the middle, reddiſh, having a heart-ſhaped appreſſed ſolitary bracte, and being terminated by a round ſpike much ſhorter than the peduncle. Spathe one-leafed ſuperior heart-ſhaped broad ſpreading at the tip, ſmoothiſh, fleſhy, pemanent. Petals five lanceolate, ſomewhat ſpreading, equal, ſnow-white; ſixth galeate, oppoſite to the nectary at top, inflated at the back, lobed on both ſides at the edge, lobes approximate ſomewhat erect at the tips; orange-colour, horned at the tip; horn erect, oblong, a little thicker at the tip and thence club-ſhaped, tomentoſe, yellow. Nectary in the diſk of the flower ſurrounded by the lower petals, ſemicylindric, obtuſe, ſmooth, ſnow-white with the edge of the blunt apex of a moſt elegant carmine colour: apex covered by a ſuborbiculate convex ſcalelet; this is membranaceous, growing cloſe to the back of the margin of the nectary, white tinged a little with roſe colour. Anthers two ſeſſile on the truncated concave body, incloſed in the ſcalelet, yellow. Silique filiform ſmooth roundiſh, with a groove on each ſide, crowned with the truncated body which is ſometimes incurved, narrower than the leaves.

98. Roots filiform, branched, ſmooth, green, paraſitical. Peduncles ſeveral, round, woody, ſheathed, jointed. Bractes double at the apex of the germ, ſubſeſſile, oppoſite ſpreading very much; ovate-lanceolate, ſharpiſh, quite entire, fleſhy, ſmooth, a little ſhorter than the germ. Inſtead of a calyx there

are ſhort white tubular ſheaths preſſed to the tube. Corolla monopetalous irregular: tube erect capillaceous, with hairs ſcattered over it, ſnow-white, long: border double, lower four-parted; lower ſegment boat-ſhaped ſpreading larger; lower apex blunt four-parted; two lateral ſegments aſcending from the tips of the larger border, acute, two within thoſe tips towards the tube faſtened to the truncated nectary, erect, lanceolate, acute, the length of the former: the other apex horn-ſhaped, aſcending, a little inflated, round, much narrower than the other and longer. Anthers ſemiglobular, double, lemon-coloured, incloſed in the cells of the nectary. Silique linear-oblong, angular, ſtriated, a little incurved, the length of the peduncle. Sometimes the lower border is five-parted to the nectary, and then the middle ſegment is broader, the lateral ones narrower.

99. Roots paraſitical filiform, round, clothed with ſcales, flexuoſe, from one bulb to another the thickneſs of a gooſe-quill, putting out briſtle-ſhaped thickiſh fibres, eſpecially below the bulbs, of a cheſtnut colour. Bulbs above the roots almoſt erect ſeſſile obovate compreſſed wrinkled, terminated by leaves, ſcarcely the ſize of a hen's egg. Apex of the root club-ſhaped, jointed, terminated by ſheaths and leaves alternate bifarious compreſſed. Scapes ſolitary from the baſe of the bulb, erect, with ſix or ſeven alternate ovate and oblong ſheaths at the baſe cloſely imbricate in two rows; the lower ones ſhort broader, the upper ones more diverging longer acute, round, with a cheſtnut-coloured nap. Bractes ſolitary or two alternate towards the middle of the ſcape; they are a foot long and not ſo thick as a gooſe-quill. Flowers racemed, diſtich, ſubalternate, peduncled. Peduncles ſpreading, round, covered with a cheſtnut nap, ſhorter than the ſpathes. Bractea preſſed cloſe, lanceolate, acute, concave, membranaceous, whiter than the ſcape, ſcarcely the length of the ſcapes. Spathe one-leafed below the peduncle faſtened to the ſcape, preſſed cloſe to the germ, lanceolate-oblong, flat with the edges curved back, ſeven-nerved, ſubvilloſe keeled on the back, fleſhy, red-ruſt-colour. Corolla irregular, conſiſting of doubled petals; the outer monopetalous, navicular, aſcending; anterior apex rounded, undivided, poſterior aſcending, three-parted; the two lateral ſegments obliquely lanceolate, a little broader, decurrent towards the anterior tip, the middle one lanceolate, the outer ſurface of all with a cheſtnut-coloured nap, the inner ſmooth, with very few hairs ſcattered over them: petals interior three; the upper faſtened by its anterior tip to the nectary, decumbent, with the other tip aſcending within the outer ſegments, oblong, concavo-convex, before the tip a little narrowed, rounded at the tip, the whole white except at the end which is ſcarlet: the two other petals are faſtened laterally to the back of the nectary, thence they are erect, lanceolate, ſmooth, white, the length of the outer ſegments but narrower. Nectary a truncated body, ſemicylindric at the baſe, the length of the flower, decurrent, thence aſcending, only half the length of the petals; ſcalelet ſemiglobular, two-celled on the inferior ſurface, covered, concave. Anthers double glands, faſtened to a filament on the edge of the back, within the cavity of the nectary, covered by the cells of the ſcalelet, yellow, ovate. Silique erect, a little incurved, club-ſhaped, round, alternately ſtreaked with hairs and naked lines, crowned with the permanent corolla, liver-coloured.

100. Roots filiform ſlightly complicated, a little flexuoſe, ſmooth, whitiſh green, very long. Stem ſcarcely any. Leaves the length of the middle finger and narrower than the little finger. Scape from the axil of the ſheath of the lower leaf laterally curved, ſpreading very much, ſmooth below the middle, cloſely ſurrounded at the baſe by ovate acute obſolete ſhort ſheaths, an inch long. Spike ſingle, ſeldom three-parted or double at the baſe, longer than the peduncle; rachis ſubflexuoſe, round, ſmooth; each flower ſpreading, ſmall, yellow. Spathe one-leafed, preſſed cloſe to the germ, ovate, acute, concave, ſmooth, green, margined, half the length of the germ. Corolla ſix-petalled, faſtened to the germ below the nectary: the two lateral ones are obliquely ovate, erect, ſmooth, yellow, three ſurrounding the back of the nectary, erect, of theſe the two more lateral ones are lanceolate, the third outer one is broader and ovate; all equal in height; the ſixth anterior towards the nectary incumbent, aſcending a little at top, rounded, the height of the former, ſometimes with three toothlets, margined, convex, having a keel within running towards the horn: inferior apex deſcending, horned, rounded, ſhorter than the germ. Filament ſingle faſtened to the truncated body, flat, membranaceous, white, ſhort. Anthers globular double pale, in the cavity of the nectary incumbent. Scalelet obcordate, divided by partitions, white, faſtened to the back of the nectary, formed of a very tender membrane, covered. Nectary truncated, ſemicylindric, concave at the tip then decurrent, white. Stigma, a large rounded aperture below the tip of the truncated body. Silique oblong, angular.

101. Roots ſimple filiform ſlender flexuoſe ſcarioſe hoary-green, faſtened to the back of the Mangoſtan tree. Stems three or more, ſometimes but ſeldom above a foot long. Spikes terminating ſolitary peduncled, cylindric acute, reſembling ſpikes of wolf's-claw Moſs (Lycopodium) but leſs thick, two inches long. Peduncle ſheathed at the baſe with double appreſſed leaflets, round, covered with heart-ſhaped ſcalelets ciliated at the edge, ſhort. Flowers ſeſſile cloſely approximating, covered with heart-ſhaped ciliate appreſſed membranaceous pale green caducous ſpathes. Corolla ſix-petalled, unequal, faſtened to a coloured germ; the uppermoſt petal ſpreading very much, preſſed cloſe to the ſpike, ovate, ſometimes obcordate, concave; the two upper lateral ones reflex towards the back of the upper one, ovate, ſmaller, the two lower lateral ones more ſpreading, incumbent on the lower, ovate, acute, very ſmall, a little thicker and more coloured, the lower petal flat, heart-ſhaped, a little leſs than the uppermoſt: the whole corolla orange-coloured. Filaments none; the two anthers included in the cavity of a very ſmall whitiſh truncated nectary, covered with an orbicular concave lid, divided by a membranaceous whitiſh partition; oblong, callous, more coloured than the corolla. Germ club-ſhaped, with very ſmall ſtreaks, of the ſame colour with the flower: ſtyle none: ſtigma over the truncated body, divided by a membranaceous partition into cells for the anthers. Nectary a little oblong cavity, callous at the edge, faſtened to the upper petal, and of the ſame colour. Silique obovate. Obſerved by Koenig at Malacca, the fifth of ſeptember 1779, on the Tamarind.

102. Roots in bundles, filiform, flexuoſe, paraſitical. Stems creeping, filiform, unequal, with a whitiſh bark. Leaves more than a palm in length, and two thirds of an inch in breadth. Bulbs ſeſſile, incumbent, ſtraightiſh, ſolitary, ovate, grooved, wrinkled, ſcarcely more than half an inch in length, yelloviſh green. Scapes ſolitary by the ſide of the bulbs, ſimple, erect, round, ſmooth, jointed, ſcaly, ſhorter than the leaves. Scales four or five ſheathing, oblong acute, tubular at the baſe, a little inflated at top, membranaceous, pellucid, ſhorter than the interſtices. Flowers at the top of the ſcape or peduncle, crowded. Spathe one-leafed, faſtened to the ſcape below the germ, ſpreading, incurved, aſcending at the tip, linear-acute, concave, quite entire, rounded at the back, ſmooth, very tender, membranaceous, white, permanent, much longer than the germ. Petals unequal; the two upper ones approximating, linear oblong, curved at the baſe and ſpreading, a little concave, ciliate at the edge nerved, having very ſmall hairs ſcattered over them, the tips very long, ſometimes two inches, pendulous, very narrow, ſtraw-coloured; the two ſide ones upright, oblong, obliquely ſharpiſh, flat, membranaceous, concolor, ſmall, ſcarcely longer than the truncated nectary; the fifth or loweſt ſpreading, boat-ſhaped, aſcending with a ſharp apex, mem-

membranaceous, ciliate, concolor, more than three times the length of the ſide ones. Nectary, a truncated ſlipper-ſhaped body, containing the parts of fructification, growing on the diſk of the flower. Aſcending apex incurved, bluntiſh, callous, fleſhy, yelloviſh, in the tip of which is a ſort of anther on a very ſhort white filament, recurved and incumbent on the nectary, haſtate, acute with blunt edges, the length of the nectary, yellow, but ſeeming deſtitute of pollen. Truncated body ſemicylindric, erect, white-membranaceous on the upper edge, rounded on the back, truncated at the tip, three-toothed, the ſide toothlets prolonged, white. Scalelet ſubglobular, fixed to the back of the nectary at top, lying on the truncated body, membranaceous, white, opening a little on the lower ſide, having a ſmall partition, and containing two ſmall oblong ſmooth yellow anthers. Piſtil none, but the truncated body. Stigma, an orbicular hole below the diſk of the truncated body. Silique oblong angular. In the morning the flowers are ſpread out, and hence two petals are long ſtraight and upright; in the afternoon they are pendulous.

103. Roots filiform flexuoſe ſimple paraſitical. Stem none. Bulbs above the roots cloſely crowded, ovate, quadrangular, wrinkled, the ſize of ſparrows' eggs. Leaves a palm long, and two thirds of an inch broad. Petioles ſemicylindric, channelled, a little twiſted, ſhort. Peduncle at the baſe of the bulb, preſſed cloſe by a ſheath, and another ſheath above the baſe, the reſt naked, ending in an umbel in an erect flat ſemicircle, with from ſix to nine flowers in one row; pedicels erect but ſpreading towards the end, a little curved to one ſide, round, ſmooth, coloured. Bractes linear-oblong, concave, acute, membranaceous, whitiſh, each ſhorter than the pedicel to which it is affixed. Corolla four-petalled, unequal; the upper petal erect, linear-lanceolate, with two teeth at the tip, and a large ovate hole at the baſe, where it appears to be tubular on account of the edges being bent back; it is white with a purple baſe, and more than an inch long; the two ſide petals are erect, obliquely lanceolate, a little incurved at the tips, the edges yellow, recurved, and ciliate with golden hairs; they are longer than the nectary and of a blood red colour; the lower petal ſpreading, ovate, acute, inflated, ſtriated, ciliate, membranaceous, ſcarcely ſo long as the ſide ones, of a yelloviſh red colour. Nectary, a truncated body, with the tip incurved, aſcending, a little callous, coloured, ſlipper-ſhaped. Anther? ſeſſile, haſtate, acute, curved, incumbent, ſomewhat fleſhy, blood-red with a yellow tip, barren. Truncated body concave in the diſk, margined, three-toothed, the back ſemicylindric, ſmooth, concave. Scalelet ſemiglobular, divided, incumbent on the diſk of the truncated body. Anther double, ſubglobular, yellow, ſmall. Germ club-ſhaped, ſtriated, ſmooth, red, ſmall. Style none: ſtigma, a round hole on the inſide of the truncated body below the diſk.

104. Roots filiform, in bundles below the bulbs on the ſtems, paraſitical, flexuoſe, ſmooth, woody, whitiſh green, ſhining. Stems ſubſcandent, variouſly branched, compreſſed a little, ſmooth, jointed, ſometimes ſheathed, ſcruginous-green, long. Bulbs at the baſe of the branches. Racemes terminating, ſimple, ſometimes a foot and half long, but ſeldom. Peduncle erect, curved a little and flexuoſe, covered with ſheaths. Pedicels ſheathed at the baſe, ſolitary alternate, remote ſimple, round, more ſlender at the baſe, ſmooth, ſnow-white. Flowers nodding. Sheaths ſolitary, ſeſſile, with ſcalelets between. Corolla boat-ſhaped, five-petalled, ſnow-white. Silique oblong with five unequal angles, ſmooth, the thickneſs of a finger, opening laterally, three-valved. It flowers in the morning, ſhutting after noon, during ſeveral days.

105. Roots fibrous flexuoſe paraſitical. Stem none. Sheaths membranaceous, ſtriated, margined, ſmooth, the breadth of the leaves, ſhort. Spike axillary, ſimple, peduncled, bifarious, erect, longer than the leaves. Peduncle erect, ſmooth, compreſſed a little, jointed in the middle, having a large oblong acute membranaceous caducous bracte; the upper one has two or three alternate ſmaller bractes. Flowers on very ſhort alternate pedicels, having involucres at the baſe, which are lanceolate ovate acute ſolitary appreſſed membranaceous whitiſh much longer than the pedicels. Corolla ſix-petalled, three outer larger, all ſpreading a little, concave, membranaceous, whitiſh. Nectary a truncate body, very ſmall, covered by an inflated ſemiglobular membrane. Anthers two twin faſtened to a ſingle filament. Silique ovate-oblong, obſcurely angular, ſmooth. Seeds very numerous, white, thrown out to a conſiderable diſtance by very ſlender elaſtic threads or hairs.

Obſerved by Koenig in a wood by Tſing near Malacca on the upper boughs of very lofty trees.

106. Stems ſcandent, branched, round, filiform, ſcaly. Flowers among the ſcales, in pairs, ſeldom ſolitary, approximating to the ſtem, ſmall. Inſtead of a calyx, an ovate, acute, keeled ſcalelet, faſtened to the germ, inflated, membranaceous, white, ſhort. Corolla ſix-petalled; three outer, almoſt erect, ovate at the baſe, with lengthened tips, ſlightly awned, equal, whitiſh, ſtiffiſh; two inner lateral, faſtened to the ſide of the nectary, erect, ovate-oblong, quite entire, rounded at the tip, flat, membranaceous, white, ſubtranſparent, much ſhorter than the outer ones; the ſixth or third inner petal is faſtened to the upper tip of the nectary, aſcending, lanceolate, recurved, a little channelled, longer than the two other interior ones, callous, yelloviſh. Truncated body very minute, white, with a bell-ſhaped ſcalelet for a lid, faſtened to the back of the nectary, membranaceous, white, containing a twin, globular, callous, yellow, elaſtic, ſmall anther. Germ linear-oblong, ſhorter than the flower, involved in ſeveral oblong acute appreſſed membranaceous white ſcales ſhorter than the germ. Style none. Stigma a little hole below the diſk of the truncated body. Silique parabolic obſcurely three-ſided ſmooth ſmall. The lid of the nectary when ripe opens elaſtically.

107. Roots filiform flexuoſe white paraſitical. Bulbs crowded ovate angular grooved pale green, terminated by two or ſeldom three leaves, the ſize of a lark's egg. Leaves dark green, ſcarcely a palm and half long and four lines wide. Scapes at the baſe of the bulbs, ſolitary, almoſt erect, thick at the baſe and as it were ſheathed by the bulb, ſhort, filiform, roundiſh, ſmooth, having two ſometimes three joints, at which are ſhort oval ſcarioſe membranaceous ſheaths, ſcarcely longer than a fiber, dark green, flexuoſe between the flowers, angular. Raceme ſimple ſubſpiked. Flowers from eighteen to thirty pedicelled remote, the lower ones more ſo, alternate. Pedicels round ſmooth, a little coloured, ſcarcely longer than the germ. Bracte ſolitary, faſtened to the pedicel at the baſe, preſſed cloſe, heart-ſhaped acute membranaceous white ſmall; beſides this there is no calyx or ſpathe. Petals, the four outer ſpreading very much, the lower and upper linear acute, a little incurved at the tip, concave, the ſide ones broader, rounded at the tips, concave, more coloured purple, all equal in length, ſomewhat fleſhy, purple at the tips the reſt white. Truncated body ſcarcely any, in its place an erect fleſhy body, erect, compreſſed, acute, incurved at the tip, rigid, white, having a groove and hole in front, ſcarcely ſhorter than the ſegments of the apex. Filament none. Anther covered at firſt, then burſting elaſtically from its membrane. Style none. Stigma a little cleft with a hole within the horn. Silique obovate, obſcurely three-ſided, with three grooves, ſmoothiſh, leſs than an inch in length.

108. Roots creeping in the ground. Stems ſimple erect round ſheathed compreſſed a little ſmooth jointed, the interſtices ſhorter than half the length of the leaf, from three to four feet long, and half the ſize of a goose-quill. Sheaths at the joints cloſely involving the ſtem, membranaceous, ſtriated, two keeled, blunt at the mouth, having one toothlet oppoſite to the leaf, a little ſhorter than the

internodes: ſheaths radical and below the middle of the ſtem ſemiovate at the mouth, keeled on the back. Flowers terminating, on two or three alternate compreſſed ſpathes, toothletted in two rows on the edge, flexuoſe naked. Calyx none but the toothlets. Corolla ſix-petalled; five outer lanceolate acute quite entire erect equal in length; of theſe three are leſs white on the outſide, and two faſtened below the baſe of the nectary, more white, with a ſemipellucid nerve, more ſlender but hardly leſs; the ſixth inner petal oppoſite to the nectary, or the border of the nectary, broad, trifid, inflated at the baſe, fleſhy, the middle ſegment wrinkled fleſhy yellow; the two lateral ſegments erect ſemi-ovate membranaceous, coloured, with cloſe purple ſtreaks. Nectary ſpreading, boat-ſhaped, oblong, margined, retuſe, keeled, rigid, ſnow-white, about half the length of the outer petals. Filaments ſcarcely any. Anthers double, diſtinct, ovate, inflated, covered with a lid or heart-ſhaped white membrane, rather large, white, not callous, another membrane is incumbent on the anthers, which is bell-ſhaped emarginate divided into two cells. Germ cylindric, leſs than half the length of the flower: ſtyle within the nectary: ſtigma, a large triangular hole below the anthers, covered by the above-mentioned membranaceous lid. The flowers are larger than thoſe of white Narciſſus.

In the ſwampy parts of thick woods near Malacca. From the name we are to preſume that this may not be ſpecifically diſtinct from n. 89.

109. This climbs variouſly on trees. Leaves from bulbs, ovate-oblong acute flat fleſhy. Scapes at the baſe of the bulbs, ſolitary or ſometimes in pairs, with ovate inflated naked membranaceous ſheaths at the baſe, covered with a ſnow-white nap, ſeldom a foot high, commonly ſhorter. Flowers ſubſpiked ſolitary alternate ſomewhat remote, ſeſſile on the germ, ſpathaceous, boat-ſhaped. Spathes ovate-oblong acute, prolonged at the tips to the length of the flower, quite entire nerved, having white hairs on the outer ſurface, naked on the inner, membranaceous. Calyx none. Corolla ſix-petalled; the three outer larger connate below the nectary above the germ, lanceolate acute quite entire, having a ſnow-white lanugo on the outſide, within naked, yellowiſh, nerved; two other petals by the ſide of the nectary, faſtened towards the truncated end, erect, lanceolate, acute, ſmooth on both ſides, yellow, ſmaller; the ſixth petal faſtened above the baſes of the nectary and incumbent on it; doubly cordate; the ſegment of the baſe cordate, quite entire, concave, with a callous-fleſhy diſk, and a few brown-blood-red dots and ſtreaks, a little larger in front, ſmooth; the outer ſegment from the boſom of the former, obcordate, acute, ſublobed with a repand edge, concave, with a callous-fleſhy diſk, and diſform whitiſh glands towards the tip; the reſt deeper coloured, brown-blood-red. Nectary proſtrate, faſtened to the larger borders, linear, aſcending, ſmooth, white, callous; at the top a truncated body. Filaments eight very ſhort and ſlender, connate. Anthers eight likewiſe connate, obovate, flat, large and diſtinct, yellow, callous *.

This having the name of Flos aeris with a note of interrogation, is ſuſpected to be the ſame with n. 2.

The above deſcriptions, though very long, are conſiderably ſhortened, by omitting ſuperfluities, by abridging what is prolix, and entirely leaving out ſome paſſages which are very obſcure and even ſcarcely intelligible.

110 to 119 are natives of the newly diſcovered iſlands in the South Seas: 110 of New Caledonia; 111, 112, 113, 114, 116, 117, 118, 119 of the Society Iſlands; and 115 of New Zealand. They are all ſuppoſed to be new, except n. 118. which is figured in Hortus Malabaricus. Forſter, in his appendix to his Florula Auſtralis, mentions another ſpecies to be found in the Society Iſles, to which he gives the name of diſtichum, n. 546.—and a ſecond, to which he does not give any trivial name.—We have to lament that we have hitherto no deſcriptions of theſe ſpecies.

Gærtner (fruct. 1. 47.) has a ſpecies, which he names E. terreſtre. He thinks it may be Angræcum terreſtre primum, Rumph. amb. 6. 112. t. 52. f. 1? which Linneus refers to E. tuberoſum.

120. Leaves ſubradical, alternate, from a grooved multangular ſheath; they are ovate-oblong, acute, waved, concave, grooved, ſtriated, entire, ſmooth, erect, a hand in length and two inches in breadth, three, four, or five. Scape ſurrounded with leaves at the baſe, ſharp-angled, ſmooth, erect, longer than the leaves. Flowers at the top of the ſcape in ſpikes, alternate, drooping, purple. Spike ſharp-angled, erect, ſmooth, about a ſpan long. A very ſhort, ovate, purple bractæ under each flower. Upper petal of the corolla ovate, reflex in the middle, grooved, emarginate, forming a helmet twice as broad as the others, having two calluſes at the baſe between the petal and the ſtyle; the two lower petals lateral, bent down at the baſe, and then bent back, linear, like the leaflets of the calyx, and of the ſame length. Capſule cylindric-filiform, twiſted, erect except at the tip, ſmooth, purple.

Native of Japan between Oſacca and Jedo: flowering in may and june.

121. Leaves radical, four or five, ſheathing, entire, ſmooth, unequal, an inch wide, a ſpan long. Scape purple, the length of the leaves. Flowers on the top of the ſcape, in racemes, ſeveral, drooping. Bractes like the leaves, gradually diminiſhing. The two upper petals equal, ovate, the length of the calyx, yellow with a purple line, concave: lower petal or lip trifid, lateral ſegments rounded, ſhorter, white with red ſtreaks, middle ſegment longer, concave, emarginate, bent in, white with a purple baſe, with two oblong purple calluſes. Capſule cylindric-club-ſhaped, a little twiſted, ſtriated, purpliſh-green, ſmooth, drooping.

Native of Japan, flowering in june.

Though this be Limodorum ſtriatum of the Flora Japonica, yet it is diſtinct from the plant of the ſame name in Kæmpf. ic. ſel. t. 2*.

122. Roots ſimple or branched, thick, ſmooth; long contorted fibres iſſuing from the lower naked part of the ſtem and from among the lower leaves, adhering firmly to the bark of the tree. Stem perennial, ſimple, one or two feet long, as thick as the little finger, crooked, the upper part covered with leaves, the lower naked, withering away at the lower extremity. Leaves approximate, imbricate, alternate, facing two ways, linear, channelled, fleſhy, ſmooth, very firm, having two or three teeth at the end, from ſix to nine inches long, and about one broad. Raceme axillary, naked, length of the leaves, the flower-bearing part flexuoſe. Flowers from five to ten, remote, facing two ways, beautifully waved and ſtriated, with various ſhades of a greeniſh yellow. Petals oval, ſpreading, equal, ſcalloped. Nectary the length of the petals: about the middle its ſides approach, forming a tube; the apex is ſomewhat pointed.—This is a very beautiful paraſite, found on trees among the Circar mountains; it flowers during the wet ſeaſon.

123. Leaves remote alternate, facing two ways, linear, channelled, ſmooth, very firm, end-bitten, jointed juſt above their ſheath-like baſe, about ſix inches long, and one inch broad. Spike before the leaf, or leaf-oppoſed, ſhort, ſtraight, thick, many-flowered. Bractes ſmall, triangular, one-flowered. Flowers ſurround every part of the ſpike, ſmall, variegated with red and yellow.—This grows in ſimilar places.

124. The root conſiſts of many fleſhy fibres, like the two laſt, but iſſuing from one head. Stem none. Leaves radical three to five, alternate, facing two ways, from one and a half to three feet long, and about an inch and half broad. Scape radical, about two feet long, three or four inches at bottom involved in chaffy ſheaths, the reſt, forming the raceme, pendulous, many-flowered. Bractes minute, one to each flower. Petals lanceolate, ſpreading, equal,

* Retzius

* Thunberg.

equal, ſtriated with roſe-colour and yellow. Nectary red, the lower lip three-parted.

Native of the ſame places; and differing but little from the aloifolium of Linneus[a].]

PROPAGATION AND CULTURE.

Mr. Miller ſays there are near thirty ſpecies of this genus, but as the plants cannot, by any art yet known, be cultivated in the ground, it would be to little purpoſe to enumerate them, though could the plants be brought to thrive, many of them produce very fine flowers of uncommon forms. He adds, that he had three ſpecies ſent him from America, which he planted with care in pots, and placed them in a ſtove, where they ſhowed their flowers, but the plants ſoon after periſhed.

[Since Mr. Miller's time numerous ſpecies of this fine and very ſingular genus have been introduced into our gardens, and ſome of them cultivated with ſucceſs by the ſuperior ſkill of modern practice, which deſpairs not of rearing and preſerving any plants where expenſe is not regarded. It requires however great ſkill and attention to overcome the united difficulties which attend the cultivation of plants which are at the ſame time of the Orchis tribe and paraſitical.

Dr. Smith ſays, we have ſcarcely ſeen any one ſpecies of this genus, except in a dry ſtate, before the year 1787, when E. cochleatum flowered for the firſt time in the ſtove, at Kew; nor was it till October 1788, that E. fragrans of Swartz exhibited its fragrant and elegant bloom in the ſame rich collection. At preſent ſeveral ſpecies are to be ſeen flowering in ſpring or autumn[b]. The following were in a thriving ſtate in the royal garden at Kew in 1794. Epidendrum Vanilla, coccineum, ſecundum, lineare, ciliare, cucullatum, enſifolium, ophioglofſoides, ruſcifolium, fuſcatum, tripterum, Barringtoniæ, nutans, ſeſſile, altiſſimum, ſanguineum, glaucum.

They are all cultivated in the ſtove, with very great heat; being moſtly paraſitical, they flouriſh beſt with fragments of half-rotten bark at their roots[c]. They may be increaſed by parting their roots, or what are commonly called offsets, of which they generally have plenty.

[2. Epigæa cordifolia. *Heart-leaved Epigæa.*
Swartz prodr. 73.
Leaves heart-ſhaped roundiſh ſerrate convex hiſpid rigid, corollas ovate.]

DESCRIPTIONS, &c.

1. It is a low plant, with a trailing ſhrubby ſtalk, which puts out roots at the joints, and when in a proper ſoil and ſituation, multiplies very faſt. The ſtalks are garniſhed with oblong rough leaves which are waved on their edges. The flowers are produced at the end of theſe branches in looſe bunches; they are white, and divided at the top into five acute ſegments, which ſpread open in form of a ſtar. It flowers in july, but does not produce fruit in England.

[Native of Virginia and Canada.

It ſeems to have been firſt introduced by Mr. Peter Collinſon in 1736[a].

2. Native of Guadaloupe[b].]

PROPAGATION AND CULTURE.

1. This plant is eaſily propagated by its trailing ſtalks, which put out roots at the joints, may be cut off from the old plant, and placed in a ſhady ſituation and a moiſt ſoil: the beſt time for this is in autumn, that the plants may be well rooted before the ſpring. If the winter ſhould prove very ſevere, it will be proper to lay a few dried leaves, or ſome ſuch light covering over them, which will prevent their being injured by froſt; and after they are well rooted, they will require no farther care but to keep them clean from weeds.

Lyſimachia ſiliquoſa glabra. *Raii. hiſt.* 862.

Stem creeping, leaves ovate acute toothed, ſiliques the length of the ſtem.

DESCRIPTIONS, &c.

Theſe plants are hardy perennials, not void of beauty; they are however commonly conſidered only as weeds, and accordingly are ſeldom cultivated in gardens, except the firſt.

In the three firſt ſpecies the leaves are ſcattered or alternate; in the reſt the lower leaves are oppoſite, but the upper alternate: the ſpecific character therefore of *oppoſite* leaves is inſufficient.

1. *Root* creeping. *Stem* upright, from three to ſix feet high, branched at top, round, and pubeſcent; branches alternate. *Leaves* alternate, running ſlightly down the ſtem, ſmooth, the edge minutely and rarely indented, the midrib whitiſh: the lateral nerves are nearly at right angles with this: and the leaves at their firſt appearance are rolled in at the edge. Flowers purple, ſhowy, growing in a kind of long ſpike; on purple peduncles, the length of the germ; bending down before the flowers open, but afterwards erect; ſeldom more than four or five blown together on the ſame ſpike: the two lowermoſt petals ſomewhat remote from each other; filaments nearly of an equal length, purpliſh, at firſt bending down, finally becoming nearly upright, ſhorter than the piſtil; anthers red, having two cavities; pollen green: germ ſlightly quadrangular, crowned by a gland; ſtyle white villoſe towards the bottom: ſtigma large, the four ſegments villoſe: capſule ſomewhat incurvated; ſeeds affixed to a very long, looſe, flexible receptacle *.

* Curtis, Linn. Pollich.

There

There is a variety of this with white flowers.

From the similitude of the leaves to those of Willow, this plant obtained the name of *Willow-herb*, or *French-Willow*. It was formerly much planted in gardens; but as it overruns all the neighbouring plants by means of its creeping roots, it has generally been cast out: however in low moist places, or in great shade, this plant will make a good appearance when it is in flower, which will be near a month, if the season be not very hot.

[It is native of most parts of Europe from Lapland to Italy. In Britain it is not common; on Maize-hill beyond Greenwich, and other places near London, it has probably got out of gardens; but in other places it is undoubtedly wild, as near Alton in Hampshire; in Charlton forest, and several other woods in Sussex, where Mr. Miller found it in great plenty, far from any habitations; about Berkhamstead in Hertfordshire; Grays, near Henley in Oxfordshire; in several parts of Yorkshire; and many places in Scotland.

Gerarde (p. 388.) informs us that he had plants of this species from Yorkshire, and that they grew in his garden "very goodly to behold for the decking up "of houses and gardens."—His description is right, but the figure is of another species.

The young shoots are said to be eatable, although an infusion of the plant stupifies: the pith, when dried, is boiled, and becoming sweet, is by a proper process made into ale, and this into vinegar by the Kamptschatdales; it is also added to the Cow Parsnep, to enrich the spirit that is prepared from that plant; as fodder, goats are said to be extremely fond of it, and cows and sheep to eat it; the down of the seeds mixed with cotton or fur has been manufactured into stockings and other articles of clothing [b].

2. This species has been confounded with the foregoing. Professor De Saussure says it differs in its woody stem, its very narrow leaves with salient glands on their edges, the much more lively colour of the flower, shorter siliques, and the air entirely different. Haller adds, that the stem is only a foot or eighteen inches in height with a branch from almost every axil; the flowers almost the same with the foregoing, but the leaves totally different.

Mont. Villars says, that the flowers do not come in a spike, like those of the preceding, but terminate the stem, and are fewer in number.

It is an alpine plant, but is common low down in the beds of the alpine torrents; as in the *Vevoise*, and the *grand Eau* near Aigle; on both of which I gathered it abundantly. Found also in Provence, Dauphiné, Savoy, &c. It flowers in july and august. Introduced in 1775 by Drs. Pitcairn and Fothergill.

3. This differs from the first species in having flowers twice the size; the leaves broader, regularly alternate not scattered, very smoothly tomentose on both sides [c]. The stem is round, eighteen inches to upwards of two feet in height and erect [d]. Both this and the first differ from the following species in having unequal corollas with entire petals; the stamens converging at the base to the style; the pistil bent down; the leaves not opposite, and when they first break forth rolled back [e].

Native of Denmark, Silesia, and Siberia.

4. *Root* full of shoots, with numerous fibres, sending out from the upper part runners of a considerable thickness, which creeping under the surface, spread widely and propagate the plant. *Stem* from three to six feet high, upright, very much branched, cylindric, somewhat quadrangular at bottom, hirsute and purplish: with soft spreading hairs, flatted at the insertion of the branches; which are like the stem, nearly upright, the upper generally solitary, alternate. *Leaves* ovate-lanceolate, the uppermost alternate, finely toothed at the edges, the serratures hooked and blunt, hirsute with soft hairs on both sides, half-stem-clasping running a little way down the stem, the middle of the base higher than the sides of it. *Flowers* large, showy, purple or flesh-coloured, somewhat bell-shaped, and hanging down a little, on peduncles, solitary, alternate: calyx upright, angular at the base, deeply divided into four segements, united at bottom by a glandular receptacle; the base within villose: petals obcordate, emarginate, with white claws, and twice the length of the calyx: filaments four nearly as long again as the other four, but the longest not half so long as the petals; anthers oblong, two-celled, yellowish or white, after shedding their dust bowed: germ oblong, villose, four-cornered, grooved, crowned with very minute glands, the corners purple; style hanging down, and longer than the stamens, crooked, white: seed-vessel three inches long, obtusely four-cornered and grooved, slightly hirsute: seeds pale brown, ovate; viewed with a magnifier on one side convex and roughish, on the other flattish and grooved [f].

Native of most parts of Europe, by the sides of ditches, ponds, lakes and rivers, flowering in july and august.

The leaves, and particularly the top shoots when slightly bruised have a delicate cool fragrance, resembling scalded codlings, whence its name of *Codlings and cream*; this fragrance is very soon lost after the plant is gathered. It is also called *Great hairy reddled Loose-strife*. Horses, sheep, and goats eat it; and if it were found to be an acceptable fodder, it might be cultivated to advantage in wet situations [g].

It varies with white flowers, and also with variegated leaves, in which state it is sometimes sold by the gardeners; but having a creeping root, it is apt to increase too much [h].

5. This invariably differs from the foregoing in its corolla, root and pubescence. The corolla is in general not more than one-third of the size; the root does not creep; and both stem and leaves are covered with numerous soft hairs, which give the whole plant a hoary appearance. The plant is also much smaller, and in general not so much branched: the leaves sessile but not decurrent, the serratures few and distant: the calyx is also very different; and the segments of the stigma are scarcely rolled back [i].

It grows in the same places, and flowers at the same time with the foregoing.

6. The *root* has, on its upper part, little buds of a bright red colour. *Stem* from one to three feet high, upright, red, cylindric, scarce perceptibly downy, sometimes branched at top, but often single. *Leaves* opposite, except the uppermost, on very short petioles uniting at the base, sharp at the end, finely serrate with unequal teeth, somewhat hooked, smooth on the upper side, on the under paler, and very slightly hairy, the downiness is just perceptible on both surfaces, according to Withering, but most underneath. The bottom leaves are often of a bright red colour. Calycine leaflets four, lanceolate, with a conspicuous midrib slightly hairy on the outside and at the edges. Petals obcordate, deeply emarginate, pale purple, veined with deeper purple lines. Stamens mostly on one side of the style, which is bowed upwards and reddish. Germ four-cornered: style the length of the stamens, thickening a little at top: segements of the stigma spreading, but not rolled back [k].

Native of Europe, in woods and hedges; sometimes in moist meadows, but more frequently in dry gravelly soils, in courts, neglected walks, and on walls; I have often remarked it on old trees, especially willows. It flowers from june to august. Mr. Hudson, marks it as biennial, and indeed it has not the appearance of being perennial, like most of the others.

This, like most of the rest, varies with a white

[b] Haller, Curtis, Withering, Lightfoot. [c] Linn. spec. [d] Krocker. [e] Linn. spec. [f] Curtis, Linn. Hudf. With. and Stokes. [g] Curtis and Withering. [h] Curtis. [i] Ibid. [k] Curtis, Linn. Hall. With. and Stokes.

corolla, as alſo with three or four leaves at each joint.

Schreber has a ſpecies under the name of *Epilobium roſeum*, which Retzius determines to be a variety of this ſpecies; to his opinion I willingly ſubſcribe, ſuſpecting that the ſpecies of this genus, as in many others, have been too much multiplied. Dr. Smith ſuſpects that it may be a variety of *E. tetragonum*. The ſame author has another, under the title of *E. parviflorum*: ſee n. 13.—and Jacquin mentions a third, which he calls *E. alpeſtre* (Hall. 996. β.).

7. One of the moſt ſtriking characters of this is the apparent ſquareneſs of the ſtalk, which ariſes from projecting lines running from the leaves down it: to this we may add the narrowneſs of its leaves; the uncommon length of its pods, and its undivided ſtigma, a character firſt noticed by Ray [t]. The lower leaves are lanceolate, the upper ones narrower, all ſerrate and ſmooth; flowers ſmall, purple.

Willich remarks, that the young leaves have livid ſpots, and that the top of the plant, whilſt tender, hangs down: he confirms Ray's obſervation, of the ſimplicity of the ſtigma. Mr. Curtis has ſometimes found a variety, with leaves nearly as broad as thoſe of the *montanum*, and placed on petioles of a conſiderable length.

Native of Europe, the Eaſt Indies, China and Cochinchina; with us not uncommon, generally met with in marſhes, and by the ſides of rivulets and ditches; as in the lane from Newington to Hornſey-wood; near Bungay in Suffolk; Alconbury in Huntingdonſhire, *&c.* flowering in july and auguſt.

Haller doubts whether this and the next be diſtinct ſpecies, from the foregoing; Scopoli on the contrary has no doubt of it. Villars affirms that this can ſcarcely be diſtinguiſhed from the preceding.

8. *Stem* cylindric, upright, ſmooth or pubeſcent, a foot high. *Leaves* ſeſſile, ſmooth, obſcurely toothed, varying extremely in breadth: in the axils of theſe appear to be bundles of ſmaller ones, which are only ſmall leafy branches. Calyx a little hairy on the outſide; petals reddiſh or pale purple, emarginate not cloven to the middle: the anthers when they are ſhedding their pollen adhere firmly to the ſtigma ſo as hardly to be ſeparated without violence, but before and after that time they do not touch it: ſtigma thick, club-ſhaped, yellowiſh white, ſlightly cloven at top into four parts. Siliques pedunculed [*].

Mr. Ray affirms that the calyx is five-parted: that it is much lower than the foregoing, the leaves ſmaller, of a darker green, and not toothed about the edge.

Monſ. Villars deſcribes it as being lower than any of the preceding, the ſtems ſingle, little branched, and half a foot high; the leaves narrow, almoſt linear, moſtly alternate, obtuſe and wider at the baſe; the flowers ſmall, pale red, emarginate. He ſays that there are intermediate ſpecimens which ſo bring together this, and E. montanum and tetragonum, that it is difficult to diſtinguiſh them; that this however is marked by the form of its leaves, the branches being approximating, and by its truncate root full of fibres: he adds, it is clear that this is not Chamænerion paluſtre of Scopoli, becauſe the petals are entire: and he is of opinion that Scopoli has given this name to the ſecond ſpecies.

Native of Europe, on marſhes, bogs, and by the ſides of lakes.

9. This is a creeping plant, flowering early in the ſpring with ſeſſile germs: it is three or four inches, or hardly a ſpan high, decumbent at bottom, then upright, and bears one or two flowers at the top. Leaves quite ſmooth, ſometimes ſlightly toothed. Siliques quite ſmooth, four or five times longer than the leaves [*].

Native of the mountains of Lapland, Denmark, Switzerland, Sileſia, Savoy, Dauphiné, Britain; as on Cheviot hills, near Settle, about Buckbarrow-well, and in many parts of Scotland, by the ſides of rivulets, and in ſandy places.

10. Stem ſtraight round ſix feet high, with aſcending branches. Leaves lanceolate, acute, at both ends, ſubpetioled. Peduncles one-flowered. Flowers ſuperior, yellow. Capſule columnar, eight-cornered, crowned with the permanent calyx. Seeds not pappoſe, allied to E. hirſutum, but in that the leaves are oppoſite, ſerrate, decurrent, ſtem-claſping.

This is a native of Cochinchina [*].

11, 12. Natives of New Zealand [†].

13. Native of Germany.

14. This is very nearly allied to E. alpinum in its ſize, habit, diſpoſition of the leaves, flowers and ſiliques: their ſtems at bottom decumbent are thence aſcending, they are ſimple, and commonly two or three inches high, the leaves are oppoſite; thoſe of E. alpinum are elliptic, obtuſe, very ſeldom toothed, the upper ones are narrower and alternate; both upper and lower are of a bright green: the leaves of this are wider, oval, ſharp, always toothed, and of a duſky green inclining to black; the flowers are bright red, a little emarginate, middle-ſized; the ſiliques are few, ſmall, at an obtuſe angle in the firſt; ſquare, very long, and ſtraight in the ſecond. They both grow on the ſummits of the higheſt mountains, near the ſnow, where the ſiliques are often as long as the ſtem. It is poſſible that they may be only varieties of E. montanum and terragonum [‡].]

PROPAGATION AND CULTURE.

Theſe plants propagate ſpontaneouſly both by ſeeds and runners: and require to be reſtrained rather than increaſed by the hand of art. They may however be admitted to advantage in remote ſhady corners, or on rock-work. They require no culture, except ſuch as is neceſſary to keep them within bounds.

EPIMEDIUM, *(of Pliny, Επιμηδιον of Dioſcorides. From επι & Μηδοι; being larger than another plant named Medium: this derivation is very unſatisfactory, but we have not a better to ſubſtitute.)*

DESCRIPTION, *&c.*

This plant has a creeping root, from which ariſe many ſtiff ſmooth ſtalks about nine inches high, ſcylindric, ſimple, near the root ſurrounded with ſcales, at top trichotomous. Leaves once and twice ternate, pendulous, heart-ſhaped ending in a point, ſerrate, the ſerratures ending in a hair, pale green on the upper ſide, gray on the under. Raceme a finger's length, naked, looſe, lateral, with three or four branchlets, uſually two-flowered, ſupported by a rufous bracte. Calycine leaflets reddiſh, nectaries yellow, longer than the petals: ſtamens ſhort, anthers acuminate: ſtigma yelloviſh, faſciated at bottom with a red ring. Seeds obliquely tranſverſe.

Native of the Alps, and Apennines; flowering in april and may, and longer in ſhady places; alſo in Japan. Mr. Miller affirms that he received ſome plants of it, which were found growing naturally in a wood in the north of England. Bingley Woods, Yorkſhire, Dr. Richardſon: and Carrock Fell, Cumberland, Mr. T. Hutton.

'This rare and ſtrange plant (ſays Gerarde) was ſent to me from the French King's herbariſt, *Robinus*, dwelling in Paris, at the ſign of the black head, in the ſtreet called *Du bout du Monde*. I planted it in my garden, but it was dried away with the extreme heat of the ſun, which happened in the year 1590, ſince which time it bringeth ſeed to perfection.'—Johnſon (Ger. emac.) adds that it grew in the garden of his friend Mr. John Milion in Old-ſtreet, and ſome other gardens about town.

PROPAGATION AND CULTURE.

It may be increaſed by the roots, and ſucceeds beſt in the ſhade, where it muſt every year be reduced, otherwiſe it will ſpread its roots, ſo as to interfere with the neighbouring plants. It deſerves a place in gardens, though not ſhowy, for its beauty and ſingularity.

Stem ſtreaked arboreſcent, fronds ſimple ſtrict ſpike-bearing.

DESCRIPTIONS, *&c.*

Roots perennial, creeping.

They are leafleſs herbs with a hollow ſtreaked ſtem, either ſimple or branched, the branchlets uſually diſpoſed in whorls; it is jointed, and the joints are ſurrounded with a toothed ſheath. The vernal ſtems uſually bear a ſort of cone and ſoon periſh, theſe are ſucceeded by others without cones, and laſting much longer. Perhaps the former are males, and the latter females, in which the ſex has not been diſcovered. Hedwig takes the little balls for the ſtigma, and the briſtles covered with duſt, converging in wet, and ſpreading in a dry ſituation, for ſtamens[a].

Linneus, Scopoli, Curtis and others conſider the powder in the ſpikes as the ſeed. M. Adanſon has removed the Horſe-tails from the Cryptogamous plants, and placed them in the family of Pines, from which they differ in every reſpect[b].

1. This grows to the height of a foot or eighteen inches, and even of three or four feet. Stem ſlender, ſcabrous, angular, the angles edged with ſhort ſpinules, ſcarcely viſible without a microſcope. Sheaths large, lax, membranaceous, yelloviſh, commonly divided into three or four deep, triangular dents; and at the baſe of the ſheaths generally twelve green acute dents coaleſce. The whorls are hardly an inch aſunder. There are twelve or

[a] Juſſieu. [b] Scop. and Curtis.

more

more (sixteen to twenty-four *Leers*, twenty-four to thirty *Scop.*) branchlets, or leaves as some call them, in a whorl; these are very slender, about five inches long, quadrangular, and beset with several other secondary whorls, having five to seven branchlets on each; so that the whole resembles a Pine-tree in miniature. The flowering spike is at the end of the frond [a].

Native of most parts of Europe, in woods and shady places; flowering in april and may. According to Linneus it is a principal food of horses in some parts of Sweden. Scopoli affirms that it is noxious to kine, making them shed their teeth, and bringing on them a diarrhœa. This is also said of the next species.

2. The naked flowering stems appear early in the spring, and soon decay: they are the thickness of a large wheat straw, a hand's breadth or more in height, upright, yellowish, with from two to five joints, covered with membranous ribbed sheaths, divided at top into numerous segments or teeth. Spike terminating, oblong, swelling, about an inch in length, throwing out a greenish powder when ripe, which moves as if it were alive, especially if it be breathed upon: every particle has three or four, rarely five fine pellucid threads, club-shaped at the end, which occasion the motion, by extending and curling themselves up. M. Adanson takes this dust to be the pollen, but Mr. Curtis could never observe any sort of explosion in it, and therefore rather inclines to think that it is the seed. The fronds, or leafy stems, as they are commonly called, appear after the others; they are a foot or more in height, durable, scabrous; the sheaths divided into numerous, pointed, fuscous dents: branchlets about eight in a whorl (seven to twelve *Lightf.* twelve to fifteen *Leers*) generally simple, but sometimes emitting a branch or two.

Native of most parts of Europe, the Levant, Japan, and North America, in corn-fields and wet meadows, flowering in march, april and may. It is a troublesome weed and difficult to extirpate; is reputed noxious to cattle, especially kine, which it affects with a diarrhœa; they do not readily meddle with it [b]. The country-people call it *Horse-pipe* and *Snake-pipe*. It is supposed to indicate subterraneous flowing waters or springs.

3. The stem is a foot or eighteen inches high, nearly smooth, channelled with five or six deep furrows; the sheaths are divided into seven or eight acute, black dents, with white edges; from these, at flowering time, come out six to ten furrowed, smooth, simple, short branchlets, becoming afterwards longer. Spike terminating, and turning black before it disperses the dust; which is very lively, when fresh from the spike.—In marshes and ditches, flowering in june.

β. has smaller fronds, almost all the branchlets having a spike at the end, but that at the end of the stem twice as large as the rest [c].

This is also injurious to kine, as Haller experienced. In Scotland they call it *Paddock-pipe*.

4. This is the largest of all the European species. The stem is three or four feet high, the thickness of a finger, and sometimes near an inch in diameter, streaked not furrowed, smooth, soft, of a pale or whitish colour at first, but blackish in decay; joints numerous; sheaths streaked, and divided into as many long, linear dents as there are branchlets in the whorl, that is from twenty-four to thirty, thirty-six and even forty; the branchlets or leaves are quadrangular and generally simple. The spikes grow distinct from the fronds on scapes, but from the same root, these come out earlier, are a foot or eighteen inches in height, and the spikes are replete with a bluesh powder [d].

Haller tells us that this species was eaten by the common people among the Romans; and Linneus affirms that rein-deer, who refuse hay, will however eat this, that it is cut as fodder for kine with a view to increase their milk, but that it is not so acceptable to horses.

Native of Europe on the banks of rivers, lakes, ponds and ditches: flowering in may and june.

5. This grows three or four feet high, and is often quite destitute of leaves, but sometimes produces a few straggling ones. The stem is smooth, channelled with twelve or more furrows, and terminated with a black oval spike. The dents of the sheath are acute and black, and of the same number with the furrows [e].

Haller is of opinion that this is only a variety of the *palustre*. Linneus and Leers suspect it to be a variety of the foregoing: but Dr. Smith affirms, that it is very distinct.

Watery places, lakes, ponds, and ditches: flowering in may and june.

6. Stems evergreen, about eighteen inches high, naked and unbranched for the most part, but sometimes emitting two or three lateral branches near the base: they are furrowed with eighteen or twenty rough, obtuse angles, and many of the joints are three inches asunder. The sheaths are black at the base and edge, and obscurely indented with as many short, obtuse teeth as the stem has furrows. The flowering-spike terminates the stem, and the sheath which immediately subtends it, is pale at the base, but black at the edge, distinctly and obtusely toothed.

This is the best species for polishing wood and metal, as being the hardest and roughest. Hence our old writers call it *Shave-grass*. It is much used by the white-smiths and cabinet-makers, under the name of *Dutch Rushes*. In Northumberland the dairy-maids scour their milk-pails with it [f]. Gerarde says, that the women scower their pewter and wooden things of the kitchen therewith, and thence call it *Pewterwort*; and that the fletchers and comb-makers do rub and polish their work with it.—A siliceous earth abounds in the epidermis. *Davy*.

Linneus informs us that it is salutary to horses, noxious to kine, who loose their teeth by feeding on it, and that sheep avoid it [g]. How this may be I know not; but I am persuaded, with Mr. Lightfoot, that the pasture must be very bad, where any cattle are compelled to eat such food.

Native of Europe, by river sides, in bogs and watery places, and in wet marshy places in woods: flowering in july and august; also of Japan.

7. We have no description of this species.—It is a native of South America.

PROPAGATION AND CULTURE.

Though the Horse-tails be inhabitants of the water, or at least flourish best where they can lodge their perennial creeping roots in a wet soil or strong clay which holds the wet, yet they will grow without difficulty in a garden, especially near water, or under a north wall, or in the shade; they require only to be kept within bounds, as they run much at the root; it is better therefore to plant them in pots, plunged in the earth, than in the open ground.

It is not so easy to extirpate them from cultivated lands. Haller says that he tried in vain to accomplish it by plowing, dunging, and other methods; and that any one who published the secret of destroying this unpropitious weed, so injurious to kine, would merit a considerable reward. I should conceive that draining lands infested with it, would have the best chance of removing the evil.

Leaves ovate-linear imbricate.
4. Eranthemum falſoloides.
Lin. ſyſt. 58. *ſuppl.* 82.
Leaves fleſhy nearly columnar linear very ſmooth, racemes axillary, they and the calyxes ſubſeſſent, tube bent back.
5. Eranthemum ſpinoſum.
Laur. cochinch. 19.
Leaves ovate oppoſite, ſtipules ſpiny, flower ſolitary lateral.

DESCRIPTION, &c.

Theſe are undershrubs or herbs, natives of the Cape of Good Hope. Leaves oppoſite or alternate. Flowers in terminating ſpikes[a].

1. The herb has the appearance of *Phlox, Lychnis*, or *Mirabilis*. Leaves lanceolate-ovate or ovate, ſharp to both ends, oppoſite, on long petioles, quite entire, ſmooth, veined, large. Stems long, terminated by one or three ſpikes from lanceolate, green, imbricate bractes; within each of theſe a long purple flower, like that of *Phlox*[b].

It has the air of *Chironia*, but ſhould be examined more carefully.[c].

2. Stem erect, branched. Leaves crowded. Racemes ſimple, very long, erect. Tube of the corolla very long, with a ſmall obtuſe border. Anthers incumbent, linear[d].

3. Leaves ſhort. Bractes ovate[e].

4. A ſhrub reſembling *Salſola*, but with axillary, pubeſcent racemes at the ends of the branches: pedicels reflex, and at the origin of each three ſubulate bractes. Calyx five-parted, with ſubulate, pubeſcent diviſions: tube of the corolla longer than the calyx, bent back in the middle; diviſions of the border ovate, acuminate[f].

5. Stem ſuffruticoſe, a foot high, ceſpitoſe, erect, with ſhort riſing branches, ſpiny ſtipules and bractes. Leaves ſmall, quite entire, hairy. Flower pale violet, ſolitary, lateral, pedunculed. Calyx two-leaved, with acuminate erect leaflets. Tube of the corolla curved at the baſe; border five-cleft, ſpreading. Filaments placed in the tube, and exceeding it in length; anthers oblong, incumbent. Style ſhort with a thickiſh ſtigma. Capſule ſuperior, ovate, two-celled many ſeeded.

Native of Africa, in the ſuburbs of Moſambique[g].

ERBRINTHUS. See *Galega*.
ERESIA. See *Theophraſta*.]
ERICA, *(of Pliny.* Ερικη *of Theophraſtus. From* ερινω, or ερεικω, *frango, to break; from its ſuppoſed quality of breaking the ſtone in the bladder.)*
Eng. *Heath.* Fr. *Bruyere.*
Lin. gen. n. 484. *Reich.* 524. *Schreb.* 659. *Tourn.* 373. *a. Juſſ.* 160. *Gærtn. t.* 63.
Claſſ. 8. 1. Octandria Monogynia.
Nat. order of *Bicornes. Ericæ* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* four-leaved; leaflets ovate-oblong, permanent.
COR. one-petalled, bell-form, four-cleft, often bellied.
STAM. *Filaments* eight, capillary, inſerted into the receptacle. *Anthers* two-cleft at the tip.
PIST. *Germ* roundiſh, ſuperior. *Style* filiform, upright, longer than the ſtamens. *Stigma* crowned, four-cornered, four-cleft.
PER. *Capſule* roundiſh, ſmaller than the calyx, covered, four-celled, four-valved: *partitions* meeting with the ſutures, (oppoſite to the ſutures *G.*)
SEEDS numerous, very ſmall.
OBS. *There are ſome ſpecies with a double calyx.*
The figure of the corolla as to ovate and oblong differs in the different ſpecies.
The anthers in ſome are emarginate; in others two-horned, or awned: included, or ſtanding out.
The ſtamens in ſome are longer, and in others ſhorter than the corolla.
The ſtigma is alſo different in different ſpecies.

ESSENTIAL CHARACTER.

Cal. four-leaved. *Cor.* four-cleft. *Filaments* inſerted into the receptacle. *Anthers* cloven. *Capſ.* four-celled.

Leaves ſpreading, flowers ſcattered, corollas ovate, ſtyle ſtanding out.

82. Erica grandiflora. *Great-flowered Heath.*
Lin. ſyſt. 470. ſuppl. 223. Hort. kew. 2. 25. Curt. magaz. 189. Thunb. mon. n. 28.
Leaves in ſixes or thereabouts acerоſe ſmooth, flowers axillary peduncled, corollas cylindric ſubincurved ſmooth, ſtyle elongated.

Place uncertain.

83. Erica tetragona.
Lin. ſyſt. 470. ſuppl. 223.
Leaves in threes, flowers in racemes pointing all the ſame way, calyx linear, corolla four-cornered oblong, ſtyle included.

84. Erica pyramidalis. *Pyramidal Heath.*
Ait. hort. kew. 3. 491.
Anthers awnleſs included, corollas funnel-ſhaped in fours, ſtyle a little protruded, leaves in fours pubeſcent.

DESCRIPTIONS, &c.

Heaths are ſmall ſhrubs, or what are commonly called underſhrubs (Suffrutices). Their leaves are very ſmall, linear, lanceolate, or ovate, imbricate

or remote, entire, ciliate or ſerrate, in ſome oppoſite, in moſt whorled, in others again ſcattered. Bractes uſually three, two of which are oppoſite. The flowers are either axillary or terminating, and variouſly diſpoſed. Corolla moſtly of a purple colour. Anthers commonly oblong, but ſometimes linear. Germ in moſt ſpecies ſmooth.

In ſome ſpecies the anthers are awned, in others creſted, in others awnleſs; in ſome they are included within the corolla, in others they are projected, or ſtand out beyond the corolla. Hence this unwieldy genus is commodiouſly divided into four ſections; and theſe are ſubdivided into ſubordinate ſections from the diſpoſition of the leaves. The incluſion or projection of the ſtyle alſo affords another diviſion of the ſpecies. The calyx in ſome is double. And laſtly the form of the corolla aſſiſts us much in diſtinguiſhing the numerous ſpecies. The campanulate and ovate forms, with their ſeveral modifications, are the predominating ones. All this may beſt be underſtood by the following table, which may be of conſiderable uſe, by exhibiting theſe material differences at one view.

Anthers awned, from 1 to 29.
——— creſted, ——— 30 to 43.
——— awnleſs, ——— 44 to 82. 84.
Anthers included, from 1 to 69. 84.
——— ſtanding out, ——— 70 to 80.
Leaves in pairs oppoſite, 1. 2. 44. 45.
——— in threes, from 3 to 19; from 30 to 38; from 46 to 55; from 70 to 75; 83.
——— in fours, from 20 to 28; from 39 to 43; from 56 to 67; from 76 to 78; 80. 81. 84.
——— more than four, 29, 68, 69, 79, 82.
Style included, from 2 to 7; from 9 to 14; 20, 21; 23 to 25; 29 to 35; 39; 44; 56 to 58; 60 to 66 f 83.
——— middling, 42, 43.
——— ſtanding out, 1; from 15 to 19; 22; 26 to 28; 36 to 38; 45; 47 to 52; 54, 55, 59, 70, 71; 73 to 82. 84.
Corolla,
Bell-ſhaped, 1; 9 to 18; 21, 22, 37, 45, 47, 55, 62, 64; 74 to 77: 80.
Bell ſalver-ſhaped, 49.
Pitcher-bell-ſhaped, 43.
Globular-bell-ſhaped, 30, 31.
Globular, 20, 48, 65.
Subglobular, 6, 50.
Roundiſh, 53.
Ovate, 2 to 4; 23, 24, 27; 32 to 36; 39 to 41; 46, 54, 81.
Ovate-bell-ſhaped, 51.
Ovate-conical, 7, 8.
Ovate-oblong, 42, 66.
Ovate-fig-ſhaped, 52.
Ovate-funnel-ſhaped, 63.
Funnel-ſhaped, 84.
Oblong, 5, 28. 78.
Cylindric, 19, 38, 59, 68, 70, 71, 72, 79, 82.
Cylindric-fig-ſhaped, 69.
Fig-ſhaped, 25, 26, 29. (I know not any other ſenſe of the word *Greſſus* but this.)
Club-fig-ſhaped, 56, 57, 58, 60.
Salver-ſhaped, 61.
Tubular, 67.
Four-cornered, 83.

This genus has within the compaſs of a few years riſen from neglect to ſplendour. Every one remembers that Mr. Pope marks it with contempt, at the ſame time that he celebrates the colour of the flowers:

"E'en the wild Heath diſplays its purple dyes."

Mr. Miller, ſo late as the year 1768, makes mention of no more than five ſorts, four of which, as being wild, he conſigns to oblivion; the fifth (n. 17.) is an inhabitant of the ſouth of Europe; but he has not one of thoſe beautiful natives of the Cape of Good Hope, which now form ſo great an ornament to our green-houſes or dry ſtoves. In Linneus's ſpecies plantarum (1762) we have thirty-eight ſorts; in Dahlgren's diſſertation, 1770, there are fifty-eight; which are increaſed to ſeventy-four in Murray's edition of ſyſtema vegetabilium (1784.) From Bergius, the ſupplement, &c. and to ninety-one in Thunberg's diſſertation on this genus, publiſhed the year following. Our liſt, by the aſſiſtance principally of the hortus kewenſis, contains eighty-three-ſpecies.

Our firſt acquaintance with the African Heaths is from Hermann and Oldenland towards the end of the laſt century. The latter of theſe authors enumerates twenty-ſix ſpecies.

Ray in his hiſtory (1688) enumerates fifteen ſorts which are chiefly our wild ones, and thoſe from the ſouth of Europe he has only one African in this liſt: in his Dendrologia, however, (1704) he has a long catalogue of fifty-ſix African Heaths, from Petiver and Plukenet, but chiefly from Sherard. This is a mere enumeration of names; and Heaths continued to be little known, except from the dried ſpecimens in the herbariums of the curious, till ſome of the European ſpecies were imported into our gardens between the years 1763 and 1770; and the rich harveſt of Africans were introduced from the Cape of Good Hope, by Mr. Francis Maſſon, who made two voyages to that ſpot, ſo abundant in rare plants, by the command and at the expenſe of the King of Great Britain; firſt in the years 1773, 1774 and 1775; and again in the years 1786 and 1787. Since theſe two periods, no genus of plants has attracted more regard than that which is now to be deſcribed.

1. Common Heath is a foot or two in height, or more; the ſtems brown and woody, very much branched; the branches in oppoſite pairs, moſtly upright, round, downy and reddiſh; the branchlets ſquare. Leaves nearly ovate, blunt iſh, with a whitiſh furrow, ſlightly hairy at the edge; according to Lightfoot tetragonal, in four imbricate rows, the uppermoſt having angles at the baſe like the barbs of an arrow. Flowers ſolitary, on peduncles the length of the leaves, from the ſides of the branches, ſlightly nodding, oppoſite, but generally pointing one way, giving the branches the appearance of long bunches, but leafy ſhoots will be always found at the end. There is a ſmall bracte at the baſe of each peduncle; and two (ſometimes three,) roundiſh-ſagittate concave bractes, woolly about the edge, at the baſe of the flower, of the ſame ſhape as thoſe of the outer calyx. This is very ſhort, compoſed of four (or five) leaflets, often tinged with red, fringed at the edge with ſoft hairs; the two outer leaflets ſomewhat larger, ovate, ſlightly keeled, the two inner roundiſh-ovate, ſomewhat membranaceous. The inner or proper calyx conſiſts alſo of four oval-oblong, concave leaflets, ſlightly adhering at the baſe, alternating with the ſegments of the corolla, of the ſame colour, and nearly of the ſame texture with them, five times as long as the outer calyx, open, but after flowering approaching, with the points bent in. We may here obſerve a curious inſtance of the gradual tranſition from the green herbaceous leaves of the ſtem, to the more delicate texture of the corolla; which is of a pale purpliſh roſe-colour, whitiſh towards the baſe, divided two-thirds of the way down into four (ſometimes five) ovate, blunt, equal, open ſegments. Filaments awl-ſhaped, double to and fro towards the point, white, or tinged with purple, ſpringing from ſmall glands at the baſe of the germ. Anthers reddiſh-brown or orange-coloured, lanceolate, having two cells opening at the ſides; horns awl-ſhaped, white, appearing woolly when magnified, ſometimes cloven, pointing downwards, nearly half as long as the anther; pollen white. Germ orbicular, but thick in proportion to its breadth, reddiſh, with eight perpendicular ridges beſet with ſoft white hairs: ſtyle ſtanting upwards, white, purpliſh above, longer than the calyx: ſtigma purpliſh red*. Capſule ſmall, involved in the permanent flower, globular, ſlightly depreſſed, partitions ſimple, faſtened

* Stokes in Wich. Wither. Curt. Lightf.

to the axis of the capſule, and oppoſite to the ſutures of the valves: receptacle globular, fleſhy, four-lobed, in the upper part of the capſule. Seeds fix to nine in each cell, ſubovate, ſcrobiculate-wrinkled, pale yellow[b].

It varies with white flowers, and with hoary leaves. The latter has been conſidered by ſome as a diſtinct ſpecies, and by others confounded with E. ciliaris. It is frequent on Bagſhot heath, Enville common in Staffordſhire, Birmingham heath, and as Ray ſays, not only about Windſor, where Cluſius obſerved it, but all over England.

This plant, which is little regarded in warmer climates, is made ſubſervient to a great variety of purpoſes in the bleak and barren highlands of Scotland, and other northern countries. The poorer inhabitants cover their cabins with it inſtead of thatch, or elſe twiſt it into ropes, and bind down the thatch with them in a kind of lattice work. They alſo make the walls with alternate layers of heath and a ſort of cement made of black earth and ſtraw. The hardy Highlanders frequently make their beds with it. In moſt of the Weſtern iſles they dye their yarn of a yellow colour, by boiling it in water with the green tops and flowers of this plant: and woollen cloth boiled in alum water, and afterwards in a ſtrong decoction of the tops, comes out a fine orange-colour. In ſome of theſe iſlands they tan their leather in a ſtrong decoction of it. Formerly the young tops are ſaid to have been uſed alone to brew a kind of ale; and Boethius relates that this liquor was much uſed by the Picts. In ſome of the iſles it is ſaid they ſtill brew ale with one part malt, and two parts of the young tops of heath, ſometimes adding hops. In many parts of Great Britain beſoms are made of it. The turf, with the heath growing on it, is cut up and dried for the fuel of the cottager, for heating ovens, covering under ground drains, &c.

Sheep and goats will ſometimes eat the tender ſhoots, but they are not fond of them. Cattle not accuſtomed to browſe on heath give bloody milk, but are ſoon cured by drinking plentifully of water. The branches of heath afford ſhelter, and the ſeeds a principal part of the food of many birds, eſpecially thoſe of the Grous kind: and for this purpoſe the ſeed-veſſel is formed and protected in ſuch a manner, that the ſeeds are preſerved a whole year, or even longer. Bees collect largely from the flowers, and honey made from them was anciently ſuppoſed to be of a bad quality, but in fact it is only of a darker colour. The foliage affords nouriſhment to the Phalæna quercus, or great egger Moth. Dodder frequently entwines itſelf about this plant, and gives it a ſingular appearance[c].

Almoſt every part of Europe abounds with heath, eſpecially the northern countries; it is alſo common in all the temperate parts of the vaſt Ruſſian empire.

Heath is called Ling in ſome parts of England, in Shropſhire Grig, in Scotland Hather. It is remarkable that Shakeſpeare enumerates Heath and Ling as different plants. The former of theſe names is from the German *Heide*, and the latter from the Daniſh *Lyng*: in Swediſh it is *Liung*; in Italian *Erica*; in Spaniſh *Brezo*; in Portugueze *Urze*, *Erice*, *Torga* or *Eſtorga*; in Ruſſian *Wereſk*.

2. The ſtem is ſubdivided into narrow branches. Leaves preſſed cloſe, almoſt imbricate. Calyx lanceolate, rounded, yelloviſh, not more than half the length of the corolla, cloſe. Corolla ovate-oblong, ſubroſtrated, yellow. Anthers and ſtyle included, Stigma truncated, four-cornered, echinate[d].

It is thus deſcribed by Thunberg. The whole is ſmooth, with a rufeſcent upright ſtem, two feet high. Branches ſcattered, from erect, ſpreading, wand-like; branchlets alſo ſcattered, filiform, very frequent, wand-like, ſhort. Leaves oppoſite, blunt, grooved underneath, a line in length. Flowers on the extreme branchlets, one, two or three together, upright. Bractes linear, obtuſe, concave, pale. Calycine leaflets ovate, acuminate, keeled below the tip. It varies with the corolla, calyx and bractes yellow or white. The whole plant being covered with its ſhining golden or ſilvery flowers, is very beautiful.

Native of the Cape of Good Hope, where it was obſerved by Bergius; and thence introduced here by Mr. Francis Maſſon, in 1774[e].

3. This is a lofty ſhrub with purpliſh branches; the branchlets ſubtomentoſe and white. Leaves crowded very much, even, rugged about the edge. Peduncles ſhorter than the leaves. Corolla purpliſh, ſmooth, diſtinct from all others in its flowers being the ſize of an acorn[f].

Thunberg thus deſcribes it. Stem ſmooth, rugged, brown, flexuoſe, decumbent, ſtrict, a ſpan high. Branches alternate, divaricate, like the ſtem. Leaves in threes, lanceolate, acute, ſmooth, flat above, convex beneath, with a ſlender groove, ſpreading. Peduncles tomentoſe, reflex. Bractes ovate, acute, approximating, many times ſmaller than the calyx. Calycine leaflets ovate, acute, keeled, entire, preſſed cloſe, ſmooth, pale, two lines in length. Corolla acute, pale fleſh-colour; the ſegments ſtraight, acute, converging; the largeſt of all the Ericas.

Native of the Cape of Good Hope. Introduced here about 1780. It flowers in may and june[g].

4. Stem ſhrubby, determinately branched, branches ruſhy. Leaves linear-ſubulate, acuminate, even, patulous. Racemes pointing one way, nodding, on peduncles the length of the flower, fleſh-coloured: bractes remote, minute, coloured. Calyx red, lanceolate, very ſmall. Corolla ovate-globular, red, with a blunt mouth. Anthers a little ſhorter than the corolla. Style included, the length of the corolla. Stigma ſubcapitate[h]. The branch continues the ſpike[i]. Native of the Cape of Good Hope.

5. According to Thunberg, the ſtem is erect, pubeſcent, leafleſs, two feet high. Branches ſcattered, frequent, ſpreading, covered with leaves, very ſhort, ſimple. Leaves in threes, ovate, obtuſe, convex beneath, with a longitudinal groove, flat above, entire, imbricate, ſmooth, ſcarcely a line in length. Flowers ſolitary, nodding, on pubeſcent reflex peduncles. Bractes ovate, keeled, acute, white, a little ſhorter than the calyx, on the middle of the peduncle. Calycine leaflets ovate, acute, concave, keeled, white, ſmooth, almoſt three times ſhorter than the corolla, which is almoſt an inch long, divided at the mouth into four very ſhort blunt ſegments. It reſembles n. 3. but has ovate, not linear leaves, corollas leſs, deeply divided, and not ſo much inflated, the flowers more copious, and the ſtem erect.—This is one of the moſt beautiful of this beautiful genus, with large white flowers. Thunberg found it in the interior part of Africa[k]. It was introduced here in 1787, by Mr. Francis Maſſon[l].

6. Stem ſtrutescent, determinately branched, with white, awl-ſhaped, decurrent lines under the ſcars of the leaves; which are linear, even, preſſed cloſe, ſcarcely longer than the interſtices. Flowers terminating, ſubumbelled, on peduncles the length of the flowers: bractes linear, minute, remote. Calyx ſcarioſe, mucoſe, a little ſhorter than the corolla, ovate, acute. Corolla blunt. Anthers ovate, ſhort. Style ſhort, cylindrical. Stigma naked.

Native of the Cape of Good Hope[m]. Introduced in 1787, by Mr. Francis Maſſon[n].

7. Thunberg deſcribes the ſtem as flexuoſe-erect, aſh-coloured, two feet high. Branches oppoſite, or in threes, cinereous-villoſe, wand-like. Branchlets filiform, ſcattered, frequent, wand-like. Leaves in threes, linear-lanceolate, beneath grooved from the revolute margins, tomentoſe-whitiſh, from erect ſpreading, curved a little. Peduncle, calyx, and corolla hirſute. Calyx ſhorter by half than the co-

[b] Gartner. [c] Penn. tour, Wither. Curtis, Lightf. [d] Linn. mant. [e] Linn. ſpec. [f] Linn. ſyſt. [g] Hort. kew. [h] Linn. mant. [i] Hort. kew. [k] Linn. ſuppl. [l] Hort. kew.

rolla, which is fleſh-coloured, oblong, ſubcampanulate, and a line in length. It varies with flowers very hirſute and hairy, red, and whitiſh fleſh-colour.

Native of the Cape of Good Hope. Introduced about 1778 by Mr. James Gordon. It flowers in may and june[a].

8. Native alſo of the Cape. Introduced in 1773 by Mr. Francis Maſſon, and flowering in may and june[b].

9. This ſhrub is about two feet high, and pubeſcent. Leaves linear, ſubciliate, erect. Flowers at the ends of the branchlets, ſubſolitary, on very ſhort peduncles. Calyx lanceolate, acute, one third of the length of the corolla, ſpreading or reflex. Corolla ſhaped like that of Lily of the valley, purple, blunt. Stamens ſhorter than the corolla. Piſtil the length of the corolla. Stigma ſubcapitate.

Found at the Cape by Bergius. [c]It is covered with beautiful flowers.

10. Stems procumbent, copious, a palm in length. Leaves lanceolate, bluntiſh, even, keeled. Flowers ſcattered, ſolitary. Calyx ſcarioſe, lanceolate, acute, ſhorter by half than the corolla; which is obtuſe, red and even. Anthers very ſhort. Stigma blunt. Native of the Cape[d].

11. The whole ſhrub is ſmooth, purple, erect, a foot high and more. Branches and branchlets trichotomous, from erect ſpreading, ſubfaſtigiate. Leaves in fours, obliquely whorled, three equal in ſituation, the fourth lower, linear, obtuſe, flat above, beneath convex, with a deep longitudinal groove, the lower ſmooth, the uppermoſt very finely ciliate, attenuated into paler petioles, imbricate. Flowers terminating, four to ten, drooping. Peduncles blood-red, longer than the leaves. Calycine leaflets boat-ſhaped, acute, pale blood-red, ſmooth, ciliate at the tip, preſſed cloſe, a little ſhorter than the corolla; which is blood-red and ſmooth. The above is Thunberg's deſcription.

Corolla globular-bell-ſhaped[e]. Native of the Cape.

12. Leaves, according to Thunberg, lanceolate, ſmooth. Flowers in racemes, directed all the ſame way. Corolla purple.

This varies, with leaves in fours[f]. Native of Portugal.

13. Native of the Cape of Good Hope. E. urceolaris of Bergius, which in ſyſt. veget. is referred to this ſpecies, n. 7.

14. Leaves ſubtriquetrous, ſmooth, ſhort, patulous. Bracteas three, having the appearance of a calyx. Flowers terminating, white. Anthers convex, blunt, black[g].

Thunberg thus deſcribes it. Stem brown, upright, a foot high and more. Branches and branchlets ſcattered and whorled, flexuoſe-erect, wand-like, aſh-coloured, tomentoſe. Leaves linear-ovate, obtuſe, very finely rugged about the edge, flat above, convex beneath, with a ſlender longitudinal groove, ſhining, preſſed cloſe at the baſe, ſpreading and recurved from the middle, a line in length. Flowers terminating, in threes, peduncled, erect. Bracteas oblong, acute, keeled, white, approximating to the calyx, imbricate, ſhaped like the calycine leaflets, which are ovate, acute, keeled, very finely rugged about the edge, white, ſmooth, nearly equal to the corolla.

15. Branches filiform, creeping. Flowers violet-coloured. Leaves ovate, acute, ciliate[h]. Theſe are both natives of the Cape.

16. This is a ſhrub growing to the height of ſeveral feet. The leaves quickly fall off. With the branches of it they make beſoms, whence the trivial name[i]. It is common in the South of Europe, was introduced here about 1770, and flowers in april and may[k].

17. This is an upright ſhrub, growing to the height of ſix feet, with upright branches covered with a white nap. Leaves very abundant, upright, ſmooth, almoſt awl-ſhaped, covering the branches, wrinkled when dry. Flowers very numerous, on the middle of the branches, ſo that the later leaves are above them; they are on branching peduncles, forming a panicle. Calyx ſingle, ſhort, with lanceolate leaflets. Corolla white, ſhort, broad, four-cleft two thirds of the way[l].

Native of the South of Europe, and the iſland of Madeira. Introduced here about 1748. It flowers from february to may[m].

Mr. Miller makes it a native of the Cape of Good Hope and Portugal, but moſt of the little he has ſaid on this genus is wrong. He ſets down E. herbacea and ciliaris as natives of England; and he gives no deſcription of any except of this, and that is imperfect and erroneous.

18. This is an upright ſhrub, with the branches growing by threes. Leaves triquetrous, even, preſſed cloſe. Flowers in a panicle, nodding, alternate, white, on white pubeſcent peduncles; with ovate, alternate, white bracteæ. Leaflets of the calyx ovate, keeled, ſharpiſh, the length of the tube. Corolla double the length of the calyx, broad, ſharp; almoſt like that of E. cubica. Anthers black, two-parted, above the throat. Style purpuraſcent, rather longer than the corolla: ſtigma blunt. Found at the Cape of Good Hope by Thunberg[n].

19. Branches round, ſmooth: branchlets pubeſcent. Leaves linear-awl-ſhaped, grooved, ſpreading, half an inch long, on appreſſed petioles ſcarcely half a line in length. Flowers axillary. Peduncles hardly half an inch long, ſometimes bifid or trifid. Bracteas three, awl-ſhaped, three-ſided. Leaflets of the calyx keeled, ſmooth, two lines in length. Corolla deep crimſon, an inch long, a little bent in, ſmooth, ſubpellucid, a little ſwelling at top, with a four-cleft mouth; ſegments broad, ſharpiſh, ſuberect. Filaments whitiſh. Anthers included, oblong, brown, bifid; awns ſubulate-capillary, the length of the anthers. Style a little longer than the corolla, red. Stigma ſtanding out, inexaſſated, very dark purple. Found by Mr. Francis Maſſon at the Cape of Good Hope; and introduced in 1774. It flowers at various ſeaſons[o].

20. Branches filiform, ramentaceous, long, ferruginous. Leaves very narrow, upright, preſſed cloſe. Flowers umbelled. Calyx ſhorter than the corolla, green. Corolla purple. Anthers with two ciliate horns, inwardly mucronate, opening in an ovate form on the ſides. Style purple. Stigma double, the upper roundiſh, the lower quadrifid. Native of the Cape of Good Hope[p]. Introduced in 1786, by Mr. Francis Maſſon. It flowers in july[q].

21. Stem ſhrubby, ſmoothiſh, with pubeſcent branches. Leaves linear, obtuſe, erect, channelled underneath, the length of the joints, hiſpid, or ſubſcabrous. Flowers umbelled, diſperſed on the upper twigs. Calyx extremely minute, if obſerved, cloſely ciliate. Corolla obtuſe. Anthers two-awned at the baſe, included. Style the length of the corolla. Stigma headed. Native of the Cape[r]. Introduced in 1774, by Mr. Francis Maſſon. It flowers from february to may[s].

22. Branches ſomewhat villoſe. Leaves linear, acute, ſpreading, ſomewhat villoſe, ciliate, with a few long hairs, glandulous at the tip, three lines long, on petioles half a line in length. Flowers axillary on the extreme twigs, on peduncles a line and a half long. Bracteas three, linear, minute, caducous. Calycine leaflets lanceolate, villoſe, preſſed cloſe, a line in length. Corolla pale red, almoſt twice as long as the calyx; tube a little ventricoſe; ſegments of the border obtuſe, erect. Filaments white, a little ſhorter than the calyx: Anthers included, oblong, blackiſh, two-parted: awns awl-ſhaped, ſhort, a little divaricating. Style a little longer than the corolla, greeniſh. Stigma thickened,

convex,

[a] Hort. kew. [b] Ibid. [c] Linn. mant. [d] Ibid. [e] Linn. ſyſt. [f] Ibid. [g] Linn. mant. [h] Linn. ſyſt. [i] Ibid. & Villars. [k] Hort. kew. [l] Haller. [m] Hort. kew. [n] Linn. ſuppl. [o] Hort. kew. [p] Linn. mant. [q] Hort. kew. [r] Linn. mant. [s] Hort. kew.

convex, black-purple. Found at the Cape by Mr. Francis Maſſon. Introduced in 1775. It flowers in march and april [1].

23. Stems ſhrubby, from nine to twelve inches high, branched, brown, ſomewhat rugged from the remains of the leaves which have fallen off: branches a little woolly. Leaves commonly in fours, but ſometimes in fives, ovate-linear, ſpreading, near the flowers preſſed cloſe to the ſtem, the edges turned in and ciliated, each hair terminating in a ſmall round gland; the upper ſurface is flat, the lower concave and white. Flowers hanging down one over another all one way, forming a little head. Peduncles downy, about the length of the flowers. Bractes three at the baſe of each flower on the upper ſide, of the ſame ſhape as the leaves of the calyx, the lowermoſt the largeſt, inſerted about a line below the calyx; the two others, one on each ſide riſing from the baſe of the calyx. Calycine leaflets from four to ſix, linear, three times ſhorter than the corolla, woolly, fringed with long hairs tipt with browniſh red globules. Corolla pale purple or fleſh-colour, varying to white; divided into four very ſhallow ſegments, which turn back. Anthers ſagittate, purple, with two white horns at the baſe, and two little apertures for the diſcharge of the pollen. Germ woolly, glandular at the baſe. Capſule villoſe, truncate.

It flowers twice in the year. Native of the northern parts of Europe, on moiſt heaths and mooriſh grounds; flowering in july and auguſt; Linneus ſays, twice in the year.

This ſpecies is not inferior to many of the foreign heaths in the beauty and delicacy of its flowers. It is diſtinguiſhed from the other Britiſh heaths, not only by the flowers growing in a kind of pendulous cluſter on the tops of the ſtalks, but by the leaves growing in fours, and forming a ſort of croſs whence the trivial and Engliſh names. Our old writers call it Low Dutch Heath or Beſome Heath [2].

24. Thunberg thus deſcribes it. Stem aſh-coloured, hiſpid, flexuoſe, erect, two feet high and more. Branches ſcattered, ſeldom in whorls, like the ſtem; branchlets filiform and capillary, ſhort, wand-like. Leaves in threes or fours, frequently four on the branches, and three on the branchlets, ſeldom all in fours, linear, obtuſe, rugged, villoſe, incurved, grooved beneath, ſpreading, a line in length. Flowers at the end of the branchlets, umbelled, two, three, or more together, abundant, blood-red, hirſute. Peduncles capillary, bracted. Calycine leaflets lanceolate, rufeſcent, hairy, very ſhort. Corolla obtuſe, villoſe.

This has its name from the pubeſcency of the flowers.

β. Leaves linear, incurved, hiſpid. Flowers among the leaves terminating, converging, ſhorter than the leaves.

According to Thunberg this varies much in the ſtem, branches, leaves and flowers. The principal varieties are theſe:—1. Hairy, with leaves in threes and the corollas very finely hairy. 2. Hiſpid, with leaves in threes, and hiſpid. 3. Villoſe, with leaves in fours, rugged, and the branches in whorls. 4. Small-flowered, with the leaves on the branches in fours, on the branchlets in threes, hiſpid, corollas minute.

Native of the Cape of Good Hope [3].

25. Stem aſh-coloured, rugged, erect, a foot high and more. Branches and branchlets in a fort of whorl, from erect-ſpreading. Leaves in fours, lanceolate-ſubulate, grooved underneath, ſmooth, imbricate. Flowers at the ends of the branches in racemes, nodding. Peduncle blood-red, villoſe, the length of the leaves. Bractes below the middle of the peduncles, ovate, acute, ciliate, keeled, pale. Calycine leaflets broad-ovate, acute, keeled, very finely ſubciliate, ſmooth, blood-red. Corolla cylindric, ſubventricoſe below the tip, a little curved, obtuſe, ſmooth, blood-red, half an inch long. Corollas according to Linneus, twice as long as the leaves [4].

Native of the Cape. Introduced in 1774, by Mr. Francis Maſſon. It flowers in june and july [5].

26. Stem ſomewhat rigid, with white awl-ſhaped decurrent lines from the ſcars left by the fallen leaves. Leaves awl-ſhaped, crowded, ſomewhat rugged on the edge. Flowers in a ſort of head, on very ſhort purple peduncles, with very ſmall remote bractes. Calyx blood-red, ovate, very ſhort. Corolla ovate-cylindric, blood-red, very long, with a blunt mouth. Anthers a little ſhorter than the corolla, two-parted. Stigma turbinate-headed, four-cornered. Thunberg ſays it differs from the preceding, in having the calyx linear, the corollas more inflated, the flowers in umbels, and the leaves in ſixes, Native of the Cape [6].

27. This is the ſize of Juniper [7]. Native of the Cape.

28. This is a brown rugged ſhrub, determinately branched, ſomewhat rigid, having the appearance of a ſmall Pinus ſylveſtris. Leaves crowded very much together, linear, acute, deep green. Spike terminating, ſurrounded by ſeſſile, imbricate, broadiſh flowers. Corollas longer than the leaves, obtuſe, commonly drooping. Stamens not ſtanding out; but the ſtigma is ſo a little. Native of the Cape [8].

29. Stem ſhrubby, upright, compound, two feet high. Leaves crowded, ſcattered, almoſt filiform, an inch long, even, capillary at the baſe, from erect ſpreading a little, glandular near the tip. Flowers terminating, faſtigiate. Calyx ſhorter, four-parted, linear, erect. Corolla cylindric, purple, with a four-cleft, yellow, upright mouth. Anthers the length of the corolla. Style the length of the ſtamens. Native of the Cape; obſerved there by Eäck [9].

30. Stem, according to Thunberg, brown, ſmooth below, hiſpid at top, erect, a foot high. Branches dichotomous, brown at bottom, and ſmooth, above aſh-coloured, hirſute, erect, faſtigiate: branchlets ſcattered all over the branches, filiform, frequent, hairy-rough, wand-like. Leaves linear-ſubulate, entire, ſmooth, flat above, convex beneath, with a very ſlender groove, incurved, from erect ſpreading. Flowers ſolitary, or two or three together, on very ſhort drooping peduncles, aſh-coloured, tomentoſe. Bractes lanceolate, ſmooth, white, ſhaped like the leaflets of the calyx; which are broad-ovate, acuminate, concave, keeled, membranaceous on the edge, entire, from erect, ſpreading, ſmooth, white, equal to the corolla; which is ſmooth, white, the ſize of a pepper-corn.—Branches and peduncles tomentoſe. Corolla the length of the calyx [10].

Native of the Cape. Introduced in 1787, by Mr. Francis Maſſon [11].

31. Stem erect, branched. Leaves linear, bluntiſh, rugged on the edge, longer than the internodes, on white petioles. Flowers terminating, in threes or thereabouts, nodding, the ſize of a pea, on purple peduncles, with alternate, remote, fleſh-coloured bractes. Calyx fleſh-coloured, lanceolate, the length of the corolla, keeled, bent in. Corolla obtuſe, red. Anthers awnleſs, very ſhort, yellowiſh. Style cylindric, ſhort. Stigma headed. Native of the Cape [12]. Introduced in 1774, by Mr. Francis Maſſon. It flowers in april and may [13].

32. Thunberg deſcribes his gnaphaloides thus. It is a ſmall ſhrub, ſmooth all over, of a cinereous brown colour, erect, a ſpan high. Branches and branchlets dichotomous and trichotomous, filiform, from erect ſpreading, faſtigiate. Leaves ovate, entire, ſmooth, flat above, convex beneath, with a longitudinal groove, preſſed cloſe, the length of the internodes, forming as it were jointed branchlets, a line and half in length. Flowers terminating, about three together, purple. Bractes approximating to the calyx, boat-ſhaped, purple, very finely ciliate,

[1] Hort. kew. [2] Curtis, Withering, Stokes in With. [3] Linn. ſpec. [4] Linn. ſyſt. [5] Hort. kew. [6] Linn. ſuppl. [7] Linn. mant. [8] Linn. ſyſt. [9] Ibid. [10] Linn. ſyſt. [11] Hort. kew. [12] Linn. mant. [13] Hort. kew.

Calycine leaflets boat-shaped, pressed close, purple, the length of the corolla; which is bell-shaped and smooth. Native of the Cape of Good Hope.

33. Stem shrubby, compound. Leaves linear, smooth. Flowers terminating, sessile. Bractes on each peduncle three, alternate, ovate, purple, the size and appearance of a calycine leaflet. Calyx spreading, with ovate, purple leaflets. Corolla purple. Stigma headed. Native of the Cape[y]. Introduced in 1774, by Mr. Francis Masson. It flowers in august[z].

34. This is a shrub with linear, appressed, smooth leaves, the length of the internodes. Flowers racemed, pedunculed. Bractes solitary, or in pairs, having the appearance and colour of the calyx; which is ovate, even, and flesh-coloured. Corolla bell-shaped, white. Stamens shorter than the corolla. Anthers brown, two-parted. Style dark purple. Stigma becoming blue at the tip. Native of the Cape[a].

35. Calyx and bractæ white. Corolla yellow[b].—Leaves three-sided. Bractes alternate. Calyx blunt[c]. The calycina of Thunberg is the same with the vespertina of Linnæus, n. 18.

Native of the Cape.

36. Root perennial, woody. Stems shrubby, about a foot high, with opposite branches; the bark ash-coloured. Leaves linear, fleshy, spreading; above smooth and shining, transversely wrinkled, towards the end beset with a few scattered hair-like points; beneath having a longitudinal furrow, which is white from a woolliness apparent to the magnifier; the edge somewhat membranaceous, and when viewed with the microscope appearing serrulate: the leaves, when young, have three flat sides, but when full grown are nearly flat. Flowers in long clustered whorled terminating spikes, sonorous when struck; they come out from the sides of the young shoots; those from the end-shoots are near each other, but scattered and bare; those from the small lateral branches generally in pairs. Peduncles shorter than the flowers, purplish brown, somewhat downy, the lower nodding, the upper upright; with a bractæ about the middle. Bractes ovate, purplish, one close to the peduncle; and three, sometimes two only at the base of each flower, the largest half as long as the calyx. Leaflets of the calyx dark purple, with membranaceous, white, serrulated edges, and a furrow along the upper half. Corolla three times as long as the calyx, bluish purple, shrivelling, and turning of a fawn-colour; the clefts very shallow. Filaments awl-shaped, ascending, doubled to and fro towards the point, white. Anthers blackish-purple, double; the horns crimson, half-ovate, the outer edge toothed, half the length of the anthers; apertures oval, oblique, extending nearly half way down the side. Germ cylindric, ribbed, smooth. Style crimson, inclining to one side. Stigma roundish. Seeds oval, the surface netted, and four times as big as those of E. Tetralix[d].

Dr. Stokes remarks, that the lower part of the trunk is free from hairiness, that the bark of the last year's shoot is ash-coloured, covered with a short light brown woolliness, and that the branches are mostly in threes. Mr. Curtis observes, that the style is inclosed within the corolla, but is longer than the stamens; and that it is distinguished from E. Tetralix, with which and the common Heath it grows promiscuously, by the fineness, smoothness, and deep green colour of its leaves; the flowers also grow more in spikes, and are of a deeper purple colour.

Native of Europe, but not in the south, nor in the extreme northern parts; also of the Levant. It flowers from june to august. It may be applied to the same purposes as the common Heath; and the flowers are much more showy.

[y] Linn. spec. [z] Hort. kew. [a] Linn. mant. [b] Linn. spec [c] Linn. syst. [d] Stokes in With. Curtis, Withet.

37. This is a shrub, with linear upright leaves, almost even. Flowers purple, very small, as are also the calyxes and peduncles; they are so abundant as to cover the whole plant. Native of the Cape of Good Hope[e]. Introduced in 1774, by Mr. Francis Masson. It flowers from february to april[f].

38. This is an upright rigid shrub, with an ash-coloured bark. Leaves in threes or fours, linear, obtuse, somewhat rugged on the edge. Flowers terminating, two or three, subsessile. Calyx rude, acute, keeled, imbricate, with similar bractes. Corolla scarcely club-shaped, obtuse, three times as long as the calyx; the segments becoming hoary. Anthers included, bifid. Stigma capitate[g]. Native of Spain and Portugal. Observed in the former by Alstroemer. Introduced in 1769, by George W. Earl of Coventry. It flowers in april and may[h].

39. Leaves patulous, broad-linear, keeled. Calyx ovate, smooth, coloured, one third of the length of the corolla, which is the size of a pea, and viscid. The flowers are at the ends of the branches in a sort of umbel. Native of the Cape of Good Hope[i].

40. Stem, according to Thunberg, brown, rugged, a foot high. Branches in whorls, like the stem, flexuose-erect: branchlets trichotomous and dichotomous, like the branches. Leaves in sixes, oblong, obtuse, incurved, above three-cornered, flat, beneath grooved, rugged especially underneath, very finely ciliate, imbricate, a line in length. Petioles ciliate. Flowers aggregate, in whorls in the middle and at the ends of the branchlets. Calycine leaflets lanceolate, ciliate, blood-red. Corolla ovate-bell-shaped, hairy-rough at bottom, blood-red. Style purple, curved, twice as long as the corolla, with the headed stigma standing out. The leaves are scattered, like those of the Lycopodium or Wolf's-claw Moss, in a sort of spiral, whence it is difficult to reckon their number[k]. Introduced in 1774, by Mr. Francis Masson. It flowers in april and may[l].

41. Thus described by Thunberg. The whole smooth, brown, erect, a foot high. Branches scattered in threes, filiform, flexuose, erect. Leaves ovate, obtuse, ciliate, flat above, convex beneath, grooved, imbricate. Flowers terminating, drooping. Bractes like the leaflets of the calyx, only not so broad, ovate, acute, ciliate, concave, flesh-coloured. Corolla ovate-globular, flesh-coloured, smooth. Native of the Cape of Good Hope.

42. Stem frutescent, somewhat rugged, determinately branched. Leaves oblong-ovate, terminated by a little bristle, convex above, smooth, shining. Flowers terminating, corymbed, subsessile. Calyx red, lanceolate, with an awn at the end. Corolla long, inflated, viscid, with a globular throat, and a four-parted acuminate, short border. Filaments linear, membranaceous. Anthers within the throat, oblong, acuminate, woolly at the base, scarcely crested, awnless. Germ oblong. Style filiform. Stigma obtuse, a little longer than the anthers. Found at the Cape by Thunberg[m].

43. Flowers terminating, four or eight from the uppermost axils. Peduncles filiform, shorter than the leaves. Bractes three, linear. Calycine leaflets, from a broad base awl-shaped, keeled, even, a line and half in length. Corolla white: tube pitcher-shaped, a little longer than the calyx; segments of the border obtuse, patulous. Filaments white, shorter than the tube, bent in at the tip. Anthers ovate, compressed, brown, two-parted: laminæ oblong, acute, sash-serrate without, white, the length of the anthers. Germ red, having eight little knobs at top. Style the length of the corolla, whitish. Stigma headed, flat beneath, convex above, commonly four-lobed. Native of the Cape: where it was found by Mr. Francis Masson. It was introduced in 1775; and flowers in may and june[n].

[e] Linn. spec. [f] Hort. kew. [g] Linn. mant. [h] Hort. kew. [i] Linn. syst. [k] Hort. kew. [l] Linn. spec. & syst. [m] Linn suppl. [n] Hort. kew.

44. According to Thunberg, the whole ſtem is ſmooth, erect, a ſpan high. Branches and branchlets filiform and capillary, erect. Leaves oppoſite, lanceolate, ſmooth, convex beneath, with a ſlender groove, preſſed cloſe. Flowers terminating, umbelled, in threes. Calycine leaflets, equalling the corolla, keeled. Flowers blood-red. Style included[a]. Native of the Cape.

45. Flowers ſolitary, terminating, peduncled. Peduncles white-tomentoſe, generally longer than the flowers. Calyx bell-ſhaped, bluntiſh, four-parted, with ovate leaflets. Corolla twice as large as the calyx. Filaments the ſhorteſt of any. Germ white-tomentoſe. Stigma ſubcapitate. This has the herb of Paſſerina Eriocoides, not to be diſtinguiſhed from it, inſomuch that Paſſerina Ericoides has entirely the herb of an Erica, with the flowers of Paſſerina. Here we have an inſtance of the intermixture of genera, which is not uncommon in the Cape plants. Native of the Cape[b].

46. Stem fruteſcent, with determinate, wand-like branches. Leaves linear, three-ſided, erect, even, longer than the internodes, ſharpiſh. Flowers in a ſort of ſpike, white, with lanceolate white bractes on the peduncle. Calyx ſcarioſe, white, ovate, acuminate, half the length of the corolla; which is white, with the belly hyaline, and the border four-parted, narrowed, acute, funnel-form. Anthers bifid, obtuſe, ſhort. Style ſhorter than the corolla. Stigma blunt. Native of the Cape[c].

Thunberg will have it, that this does not differ from lutea, n. 2. but that has oppoſite leaves; in this they are in threes.

47. A ſmall ſhrub with narrow branchlets. Leaves ovate-oblong, three-ſided, channelled. Flowers terminating, nodding, ſeſſile. Calyxes globular, waved, imbricate, with roundiſh ſcales, keeled and bent in at the tip, blood-red. Corollas bell-ſhaped, yelloviſh, ſcarcely longer than the calyx. Style very long, nodding[d]. Native of the Cape. Introduced in 1774 by Mr. Francis Maſſon[e].

48. Thunberg thus deſcribes it. Stem ſeldom erect, commonly decumbent, ſmooth, flexuoſe, filiform. Branches filiform, flexuoſe, villoſe; branchlets capillary, frequent, tomentoſe. Leaves ovate, ſpreading, rough, with long hairs. Flowers at the ends of the extreme branchlets, peduncled, one, two or three together, the whole calyxes covered cloſe with a white wool. Anthers protruded, purple. Style protruded, a little above the anthers.

Linnæus, in his Species plantarum, ſays that this is known by its globular flowers, covered with a greeniſh yellow lanugo. Corolla half-five-cleft, obtuſe, not longer than the calyx. Anthers included[f]. Native of the Cape. Introduced in 1774, by Mr. Francis Maſſon. It flowers from april to july[g].

49. Stem ſhrubby, flexile. Leaves linear, obtuſe, even, patulous. Flowers terminating, ſubumbelled, ſcattered in cloſe parcels, nodding a little. Peduncles the length of the corolla, purpliſh. Bractes lanceolate, alternate, coloured. Calyx blood-red, obovate, more in breadth than length, keeled, with a dagger point at the tip. Corolla bell-ſalver-ſhaped, blood-red; tube the length of the calyx; border ſpreading, generally longer than the tube, the ſegments roundiſh-ovate. Anthers dark-coloured, bifid, the length of the border. Style twice as long as the corolla, briſtle-ſhaped. Stigma blunt, ſlightly four-cornered. Native of the Cape[h].

50. Stem ruſeſcent, round, ſeldom branched. Leaves linear, even, ſeſſile, acute, generally preſſed cloſe. Flowers terminating, peduncled. Bractes two, alternate, ſcarioſe, lanceolate. Calyx even, with ovate, ſcarioſe, acute, yellow leaflets. Tube of the corolla ſubglobular; border four-parted, the length of the calyx, with ovate, acute, ſpreading ſegments. Anthers purple, bifid, ſtanding up above the throat. Style longer than the ſtamens. Stigma ſimple, obtuſe. Found at the Cape by Thunberg[i].

[a] Linn. ſyſt. [b] Linn. ſuppl. [c] Linn. mant. [d] Linn. amoen. & ſyſt. [e] Hort. kew. [f] Linn. ſyſt. [g] Hort. kew. [h] Linn. mant. [i] Linn. ſuppl.

51. This ſhrub has the ſtature of Wormwood, and is panicled. Stem rufous; branches in threes. Leaves linear, gibbous on the outſide, ſubhirſute. Flowers at the ends of the branchlets. Corollas pale. Anthers very dark purple, bifid, within the mouth of the corolla. Stigma purple, four-cleft. Native of the Cape[a].

Thunberg ſays it varies 1. With a wand-like ſtem, and branches and leaves very hirſute and rugged. 2. With a wand-like hirſute ſtem and branches, and wrinkled villoſe patulous leaves. 3. With a panicled ſtem, very ſhort branchlets, and the leaves a little rugged and hirſute. 4. With a panicled ſtem, longer faſtigiate branchlets, and the leaves a little rugged and ſmooth.

52. This is a ſuffruticoſe plant, two feet high. Leaves ſpreading very much, ſeſſile, ovate, acute, reflex and ciliate on the edge. Raceme terminating, whorled by threes. Corolla large, with a contracted unequal mouth[b]. According to Thunberg, oblong, bell-ſhaped, white. Anthers purple. Style almoſt twice as long as the corolla. Native of Spain and Portugal. Introduced about 1773. It flowers from july to ſeptember[c]. Caſpar Bauhin gives it the epithet of Engliſh; no one, however, has heard of its being found in our iſland, though Mr. Miller has fallen into Bauhin's error, and ſets it down as one of our wild plants.

53. Stems decumbent, half a foot high, ſtrigoſe or hairy. Leaves ſubſeſſile, horizontal, patulous, even. Flowers ſmall, bell-ſhaped, bent towards the ground, ſcattered thinly. Style longer than the corolla. Thunberg ſays it much reſembles the plantaginifolia, but differs in having an erect ſhrubby ſtem, awnleſs anthers, the leaves ſcarcely ciliate, revolute, more approximating, the corollas globular and ſmooth.—Native of the Cape of Good Hope[d].

54. Stem round, flexuoſe, decumbent, rigid, ſmooth. Branches ſcattered, oppoſite, or by threes, almoſt erect, bent in, flexuoſe, tomentoſe at top. Leaves lanceolate, flat above, grooved beneath from the revolute margins, entire, ſmooth, ſpreading. Petioles ſemicylindric, the length of the leaves, equalling the internodes, preſſed cloſe, pale. Flowers terminating umbelled, on very ſhort tomentoſe peduncles. Bractes lanceolate, towards the baſe of the calyx. Calycine leaflets, ovate, acute, entire, ſmooth, concave, keeled below the tip, preſſed cloſe. Corolla bell-ſhaped, pale, ſmooth. Native of the Cape. Introduced in 1774, by Mr. Francis Maſſon. It flowers from March to june[e].

55. Stem erect, ſmooth, a foot high and more. Branches commonly in threes, pubeſcent, erect, wand-like: branchlets ſcattered, very frequent, filiform and capillary, pubeſcent, erect, leafy. Leaves three-cornered, obtuſe, preſſed cloſe, ſmooth, with a very ſlender groove underneath. Flowers on very ſhort peduncles, erect. This is diſtinguiſhed by its white corolla, and awnleſs, projected, white anthers. Found at the Cape by Thunberg[f].

56. Leaves linear, even, the upper one ciliate. Flowers terminating, ſolitary, ſeſſile. Corollas purple, acuminate, pubeſcent, ſeveral times longer than the calyx, the ſegments lanceolate. Style ſcarcely projected. Native of the Cape[g].

57. This is allied to the preceding. The corollas are pubeſcent, with the ſegments lanceolate-awl-ſhaped; but the branches are hairy, and the leaves are ſmooth. Native of the Cape[h].

58. Flowers copious. Corollas pubeſcent. Native of the Cape[i].

59. Found at the Cape of Good Hope by Mr. Francis Maſſon. Introduced in 1774. It flowers from may to auguſt[k].

60. Branches compound. Leaves oblong, convex, even, grooved underneath, ciliate, with ſpinules. Flowers large, heaped on the ſide into a ſort of head, ſeſſile, pubeſcent. Calyx rough, with

[a] Linn. mant. [b] Linn. ſpec. [c] Hort. kew. [d] Linn. ſuppl. [e] Hort. kew. [f] Linn. ſuppl. [g] Linn. ſpec. & ſyſt. [h] Linn. ſyſt. [i] Hort. kew. [k] Ibid.

white

white hairs, as it were doubled. Corolla bright blood-red, rough alſo, with white hairs, having the mouth obſcurely four cleft. Native of the Cape [k]. Introduced in 1774, by Mr. Francis Maſſon. It flowers moſt part of the year [l].

61. This is a ſmall ſhrub with even branches, ſtreaked in four rows. Leaves linear, acuminate, three ſided, even, rugged about the edge, erect, the length of the internodes, but the upper ones longer. Flowers erect, faſtigiate, terminating. Calyx ſimilar to the leaves. Corolla with a cylindric patulous tube, a little longer than the leaves; border flat, red above, white underneath, the four ſegments ſubcordate. Stamens ſhorter than the corolla. Anthers ſcarcely emarginate. Native of the Cape [m].

62. Stem ſhrubby, determinately branched. Leaves ſpreading, linear, acute, longer than the internodes, ſlightly incurved, on white petioles. Flowers terminating, corymbed; on ſubtomentoſe peduncles, having briſtle-ſhaped bractes in the middle. Calyx ſcarioſe, with the leaflets obcordate, complicate, keeled, bent in and rude at the tip. Corolla half-four cleft, purple, with a pale baſe, twice as long as the calyx. Anthers two-horned at the tip, acuminate, very ſhort. Style the length of the corolla. Stigma obtuſe. Native of the Cape [n].

63. Stems diſtorted, as in common Heath. Leaves crowded together, ſpreading a little, ſubcylindric, even. Flowers in terminating bundles. Calyx doubled. Tube of the corolla oblong-ovate, the ſegments ovate, obtuſe, ſpreading. Anthers not longer than the corolla, almoſt included. Stigma obtuſe. Obſerved at the Cape by Bergius [o].

64. Stem determinately branched. Leaves linear, erect, acute, longer than the internodes, rugged at the edge. Bractes calycine, rude, approximating. Calyx rude, awl-ſhaped, half the length of the corolla; which is purpliſh, with the ſegments erect and acute. Anthers biſid, with a cavity on the outſide, and very ſhort. Style ſhorter than the corolla, but twice as long as the ſtamens, purple. Stigma headed, four-lobed. Germ hirſute. Native of the Cape [p]. Introduced in 1774, by Mr. Francis Maſſon. It flowers in march [q].

65. This reſembles E. ramentacea in the plant, (and Thunberg makes it to be the ſame): Stem determinately branched. Leaves linear, erect. Flowers terminating, few, peduncled. Calyx ſcarioſe, very ſhort. Corolla red. Anthers rugged, biſid at the tip as it were two-horned. Stigma headed. Native of the Cape [r].

66. Branches heaped above the flowers. Leaves linear, bluntiſh, erect. Flowers heaped, lateral, below the top of the ſtalk. Calyx ſcarioſe, ſubdiaphanous, bluntiſh, erect. Corolla like that of E. albens, with a flat ſharpiſh border. Anthers very ſhort. Stigma headed. Native of the Cape [s]. Introduced in 1787, by Mr. Francis Maſſon [t].

67. This is remarkable for having the flowering heads always divided into four flowers; before theſe are elongated, the head appears globular, and echinate, as in Achyranthes, from the very ſpreading yellow briſtles of the leaves of the involucre and calyx. Corollas extremely hirſute, with a four-cleft mouth, the ſegments very ſhort. Obſerved by Sparrmann far inland from the Cape of Good Hope [u].

68. Branches ſmooth. Leaves on the branches in fives, on the branchlets in fours, petioled, erect, acerоſe, four lines in length. Petioles ſmooth, ſcarcely half a line long. Flowers from three to ſix in an umbel. Peduncles filiform, ſomewhat hairy, two lines in length. Bractes three, awl-ſhaped, ciliate, preſſed to the calyx. Leaflets of the calyx from a broad baſe awl-ſhaped, ciliate, grooved, two lines long. Corolla fleſh-coloured, ſomewhat villoſe on the outſide, ſcarcely an inch long, the thickneſs of a fowl's quill. Filaments ſmooth, a little ſhorter than the tube of the corolla. Anthers oblong, acuminate at the baſe, two-parted at top as far as the middle, where they are fixed to the filaments; they are awnleſs, and of a brown colour. Germ turbinate, concave, above, crenulate on the edge. Style red, the length of the ſtamens. Stigma ſubcapitate, very dark red. Obſerved by Maſſon at the Cape of Good Hope. Introduced in 1773. It flowers in ſeptember and october [x].

69. Stems ſhrubby, filiform, covered all round with leaves. Leaves in fours, imbricate in eight rows, very ſhort, elliptic, crowded, obtuſe, ciliate, ſo that they appear villoſe. Flowers in a terminating ſeſſile head. Calyx ſhorter, linear, hairy. The corolla has a four-cleft, erect, ſharpiſh mouth. Piſtil the length of the ſtamens, which are ſhorter than the corolla. Obſerved by Back at the Cape [y]. Introduced in 1787, by Mr. Francis Maſſon [z].

70. Leaves linear, crowded. Flowers peduncled, nodding. Calyx ſhorter by half than the corolla, awl-ſhaped, keeled. Corolla long, with the mouth obſcurely four cleft. Stamens almoſt membranaceous, linear, obtuſe, twice as long as the corolla [a]. It reſembles the following ſpecies, but the calyx is ſimple, and the corolla obſcurely four-cleft and red [b]. Native of the Cape. Introduced in 1774, by Maſſon [c].

71. This is a brown ſhrub. Branches covered with branchlets in threes, crowded, very ſhort, pubeſcent, clothed with ſquarroſe leaves; which are alſo crowded, awl-ſhaped, ſubtrigonal, ſomewhat rugged at the edge, patulous, or ſtanding out at the tip. Flowers ſolitary, at the ends of the branchlets drooping, on a ſhort, pubeſcent peduncle. Calyx ſubcartilaginous, angular, imbricate, with ſimilar but ſhorter bractes, in threes. Corolla cylindric, three times as long as the leaves, with a four-cleft, acute, yellow mouth. Anthers linear, twice as long as the corolla, biſid at the tip, without any apparent filaments. Style filiform, longer than the anthers. Stigma ſimple. In the corolla and ſtructure of the ſtamens it reſembles the preceding; but the calyx is imbricate, not ſimple; the corolla yellow, more deeply four-cleft and ſharpiſh, not red, obſcurely four-cleft and obtuſe; the leaves awl-ſhaped, ſubſquarroſe-imbricate, not linear, diſtant and erect. Native of the Cape [d]. Introduced 1774, by Maſſon. It flowers from january to march [e].

72. Stem ſhrubby, determinately branched, round, twiſted: bark covered with a white nap, chinky, deciduous. Branchlets very many, erect, leafy, many-flowered very cloſely tomentoſe. Leaves on ſhort petioles, from erect ſpreading, linear-lanceolate, bluntiſh, beneath gibbous, grooved, above ſomewhat concave, on both ſides ſmooth, very minutely dotted; the younger ones ciliate at the baſe. Flowers numerous, axillary, peduncled, nodding a little. Peduncles the length of the leaves, capillary, pubeſcent. Bractes none. Calyx ſimple, ſmall; leaflets ovate-lanceolate, acute, keeled, gibbous at the baſe, ſmooth. Corolla bell-cylindric, half the length of the peduncles, almoſt four times as long as the calyx, ſmooth, four-cleft at the edge; ſegments ſmall, blunt, upright. Filaments erect, parallel, capillary, ſmooth. Anthers erect, ſemibiſid; the lobes blunt, divaricating, opening at top on the inſide with a roundiſh pore, gibbous within at the baſe, and ſmooth. Germ ſmall, roundiſh. Style longer than the ſtamens, capillary. Stigma headed-blunt. Native of the Cape. Known only by a ſingle ſpecimen in the Linnean herbarium [f].

73. Leaves linear, remote, patulous, with a few hairs ſattered over them. The calyxes clothed with a white wool cover the whole ſubtruncate corolla. Native of the Cape [g].

Thunberg makes this to be the ſame with the capitata.

74. Flowers lateral, white. Corolla covered with the white calyx. Native of the Cape [h].

[g] Linn. ſpec. & ſyſt. [h] Linn. ſyſt.

75. This little ſhrub has the habit of common Heath. Leaves ſhort, ſmooth, with a white line underneath. Umbellets naked, without an involucre. Calyx compound. Corolla pale blue, angular. Anthers gibbous-tailed at the baſe. Native of Portugal[1].

76. Leaves in threes or fours, but on the upper branchlets in fives, according to the obſervation of Seguier. Calyx awl-ſhaped. Corollas cylindric. Anthers deeply bifid[2]. Native of the South of Europe.

77. Stem like that of Empetrum, ſhrubby, ſomewhat rugged; the extreme branches whitiſh and divaricating. Leaves in fours, ſeldom in fives, linear, bluntiſh, ſometimes ſmoothiſh, ſometimes a little rugged, beneath convex and channelled, ſhortiſh, crowded. Flowers on the ſides of the branchlets, ſcattered, peduncled. Calyx coloured, erect, concave, very ſhort. Corolla blunt. Anthers without any tail, two-parted. Stigma ſimple. It reſembles E. herbacea, which however has the branchlets even, the leaves ſharp, the corollas ovate ſharpiſh, the calyxes ſpreading, half the length of the corolla, the anthers linear, acute, twice as long, and not gibbous at the baſe. Native of Africa, and alſo of the neighbourhood of Thouloufe[3]. See n. 80. which is ſuppoſed to be the ſame.

78. This is a ſmall ſhrub, from a foot to eighteen inches in height, decumbent at bottom, then upright, branched, flexible. Leaves almoſt covering the whole ſtem, deciduous, reſembling thoſe of the fir, thickiſh, having a prominent nerve, narrow, very ſharp, ſmooth. Flowers at the tops of the branchlets, on ſhort peduncles, alternate, among the leaves. They come out in autumn, continue cloſed during winter, and are then green; in may the year following the flowers are unfolded, the anthers which were incloſed are protruded, the calyx and corolla opening are both changed into a pale purple or fleſh-colour[4]. Hence many authors, among whom is Linneus, have made two ſpecies of this. The calyx is four-cleft, with lanceolate ſegments. The corolla is larger than the calyx. And the capſule is globular[5]. Native of Auſtria, Switzerland and Sileſia. Introduced in 1763, by the Earl of Coventry[6].

79. Stem the height of a man. Leaves in fours or fives, ſpreading, obtuſe, gibbous at the baſe. Flowers purpliſh[7]. Native of the ſouth of Europe. It flowers from june to november[8]. Linneus ſets this down as a native of England: but our plant which he ſuppoſed to be the ſame with his multiflora is the next ſpecies.

80. Stems twiſted, trailing. Branches between ſcored and angular, light reddiſh brown, the more ſlender ſhoots aſh-coloured, all lateral, to ſeven or more riſing from the ſame point in the manner of an umbel, in ſome ſtates of its growth giving it much the appearance of Euphorbia Cypariſſias; when beginning to flower, gradually tapering towards the end. Leaves linear, ſomewhat like thoſe of fir, bowed ſideways, ſmooth, but not gloſſy, ſomewhat pointed, when magnified appearing to have diſtant ſerratures on the edge, which is bent in, upper ſurface green, ſlightly elevated in the middle, under whitiſh, convex, with a ſmooth furrow running along it, longer, and ſometimes thrice as long as the corolla, and crowded ſo cloſe as to conceal the younger ſhoots. Petioles ſhorter and narrower than the breadth of the leaf, flat, generally ſmooth, but ſometimes ſlightly downy, preſſed to the branch. Flowers roundiſh, on long ſlender peduncles, from the ſides of the branches, beginning from below the middle, and extending to the ends, continuing on, at leaſt in the cultivated plants, till the next ſeaſon. Peduncles ſlender, capillary, from the baſe of the leaves, nearly upright, and as long as the leaves, three or four riſing from a kind of ſcaly bud, compoſed of lanceolate-ovate yellowiſh ſcales fringed at the edge, three to each peduncle, two a little below the middle, oppoſite; the third a little below. Calyx without bractes at the baſe as in the other Britiſh ſpecies; ſegments ovate, concave, the edges bending inwards, appearing fringed when magnified, divided to the baſe. Corolla truly bell-ſhaped, pointed at the baſe, cloven near half way down, ſegments broad, ſoon coming to a bluntiſh point, ſpreading, generally of a pale fleſh-colour, approaching to white, but ſometimes with a deep tinge of purple. Filaments capillary, ſomewhat flatted, white, as long as the corolla. Anthers juſt projecting, two to each filament (or ſo much divided as to appear like two), ſpreading, ovate, blunt, blackiſh brown or purple, with an oval orifice on the outer ſide extending nearly half way down. Germ roundiſh, ſmooth, with four deep furrows. Style as thick again as the filaments. Stigma juſt thicker than the ſtyle, the end flat. Seeds reddiſh brown.

Found on heaths, as on Goon Hilly downs, going from Helſton to the Lizard point in Cornwall. It flowers from june to auguſt[9]. The ſame with E. vagans. n. 77.

81. Branches whitiſh, angular. Leaves in fours, ſeldom in fives, even. Flowers lateral. Calyx ſimple, coloured, lanceolate, acute, ſhorter by half than the corolla. Style twice as long as the corolla. Stigma entirely ſimple. It reſembles E. multiflora, but the corolla is abſolutely ovate; the branches angular and white[10].

Native of the South of Europe. Introduced about 1765 by Mr. Joſhua Brooks. It flowers from march to may[11].

82. This reſembles E. curviflora, but the leaves are longer. Obſerved at the Cape of Good Hope by Thunberg[12]. Introduced here in 1775 by Maſſon. It flowers from may to july[13].

83. Flowers yellow, like thoſe of E. lutea, but longer. Native of the Cape[14].

84. Introduced from the Cape by Maſſon in 1787[15].

PROPAGATION AND CULTURE.

1. Common Heath, which over-runs immenſe tracts, eſpecially in the elevated parts of northern countries, can be extirpated only effectually by paring and burning. In ſome lands, deep and croſs ploughings, getting up roots with heavy harrows, burning the whole, and ſpreading the aſhes may be ſufficient[16].

Dr. Anderſon affirms that wherever Heath abounds, there is generated, by the rotting of the plant, a peculiar black earth, that is not only of itſelf ſterile, but has a powerful tendency to make any other ſoil unfertile: ſo that in improving heathy grounds, the top ſoil ſhould be buried by trenching or deep ploughing†.]

1. 23. 36. 80. Notwithſtanding the commonneſs of our Britiſh heaths, they deſerve a place in ſmall quarters of humble flowering ſhrubs, where by the beauty and long continuance of their flowers, together with the diverſity of their leaves, they make an agreeable variety. They may be taken up, with a ball of earth to their roots, from the natural places of their growth, in autumn. The ſoil ſhould not be dunged, and the leſs the ground is dug, the better they will thrive, for they commonly ſhoot their roots near the ſurface. They may alſo be propagated by ſeeds, but this is a tedious method.

[12. 16. 17. 38. 52. 75—79. 81. Theſe, which are natives of the ſouthern countries of Europe, will bear the open air in England in a dry ſoil and a warm ſituation. They may be increaſed and treated in the ſame manner with our Britiſh Heaths, and may alſo be propagated by layers and cuttings.

All the reſt of this numerous and beautiful genus being natives of the Cape of Good Hope, or the more interior parts of Africa leading to that famous promontory, muſt be preſerved in the dry ſtove,

Greea

green-houſe or glaſs caſe. Theſe may be increaſed either from cuttings or from layers. There are not many of the ſpecies but what may be increaſed in the firſt way, provided good young ſhoots can be got for cuttings; eſpecially if they are put under bell-glaſſes, and the pots are ſet where they can be ſhaded, and have a moderate heat. E. empetrifolia, articularis, halicacaba, faſcicularis, Maſſoni, petiolata, retorta, and a few others, have not yet been ſtruck from cuttings: theſe therefore muſt be increaſed from layers, which however will not always ſtrike the firſt year. Theſe plants ſhould have a light and rather poor ſoil to grow in; a compoſition of bog earth and light loam will ſuit them well.

Mr. James Donn, the Curator of the botanic garden at Cambridge, has collected upwards of ſixty of theſe Cape Heaths, which he cultivates this year 1795; though he was appointed to his office only at michaelmas 1794. In the 5th edition of his catalogue the number is increaſed to 312.

Leaves linear, tomentoſe, toothed a little, flowers corymbed, ſtem ſhrubby.

DESCRIPTIONS, &c.

1. Stem upright, ſtiff, ſtriated, hairy, viſcid, branched from the very bottom. Leaves ſtem-claſping, thick, rough, with hairs, having glands between them exuding a clammy juice, ſtrong ſmelling, bent down at the baſe, rounded and ſtem-claſping: on the branches linear, entire. Peduncles two-leaved, one-flowered, ſcarcely longer than the leaves. Flowers radiate. Seeds pubeſcent*.]

Root perennial. Stems near three feet high. Leaves alternate, four inches long, and two broad in the middle. Flowers ſingle, on pretty long foot-ſtalks, ſome from the ſide, others from the end of the ſtalk; they are yellow, have an agreeable odour, and appear in july.

[Native of the South of France, Italy, Sicily, Portugal and Spain, by way ſides, and on the borders of vineyards. Cultivated by Mr. Miller before 1759. It is uſed to drive away fleas and gnats; the ſtrong ſcent, as ſome ſuppoſe, being diſagreeable to thoſe inſects; but it is probable they are caught by the clammy juice of the leaves and ſtalks *.—The old name of this is *Great Sweet Fleabane*, or *Great Fleawort*.

2. Root annual. Stems upright, purpliſh, hairy and viſcid, from eight or ten to eighteen inches in height, ſtriated, branched the whole length. Branches patulous, at bottom longer, alternate, ſimple, crowded, all flowering. Leaves ſeſſile, narrow-lanceolate, quite entire, a little ſcabrous, with very ſmall hairs viſcid at the end ſcattered over them,

* Linn. ſpec. mant. ſyſt. & Gouan illuſtr. * Mill. fig.

ſtrong-

ſtrong-ſmelling, of a ruſſet duſky colour. Peduncles at top lateral, ſolitary, with leaflets longer than the flowers ſcattered over them, one-flowered, ſometimes two-flowered, and then one is very ſhort. Calyx oblong, with patulous, upright leaflets, purpliſh at the end before flowering time. Corolla yellow, ſmall, with a minute upright ray of five or ſix florets, purpliſh underneath. Down ruſeſcent [b]. Monſ. Villars thinks that this ſpecies rather belongs to the genus Solidago.]

The ſtalks are in gardens ſtiff, and three feet high. The flowers are produced in cloſe bunches from the ſide of the ſtalk towards the top; they appear in july, and in warm ſeaſons the ſeeds ripen in England.

[Native of the South of France, and Italy; very frequent near Madrid.—Called formerly *Small true Fleabane.* Cultivated by Mr. Miller in 1768.

3. Root perennial. Stems a long ſpan in height, ſlender. Leaves quite entire, narrow and ſharp, villoſe and glutinoſe. Peduncles alternate, one-flowered, few in number; ſemiflorets twenty and more in a flower [a], purple.—South of France and Spain, on mountains near the coaſt; flowering in auguſt.

4. Annual. Stems red. Flowers without any ray, ſmall. Peduncles covered with linear, recurved, minute leaves. It greatly reſembles the ſecond ſpecies, except that it has no ray whatever; and it is allied to Inula pulicaria.—In Sicily, and about Montpellier in marſhes [c]. It flowers in auguſt and ſeptember; and was firſt introduced in 1779, by John Fothergill, M. D. [d]

5. Stems three feet high and more, ſtraight, round, ſtreaked, the thickneſs of the little finger at bottom, where they are red, growing gradually more ſlender upwards; the leaves from top to bottom are frequent, very narrow, and ſomewhat hairy. Towards the top the ſtem puts forth branches, forming in the whole a ſort of pyramid; theſe are covered with leaves like thoſe of the ſtem, only ſhorter and narrower; each of theſe bears one ſmall flower, ſometimes more. The root-leaves are like thoſe on the ſtem, only ſhorter and blunter.—It flowered in the green-houſe of the Eltham garden in november 1727 [e]; but being a native of North America, it is hardy enough to flower in the open ground in july and auguſt. It is perennial.—In the text of *Hortus Elthamenſis* this is marked fig. 393. but on the plate fig. 394.

6. Root annual. Stem firm, hairy, ſometimes three or four feet high, frequently crooked, much branched towards the top, and even from the middle, the branches gradually ſhorter, and forming a long cone. Lower leaves oval, tapering to a foot-ſtalk, with large blunt diſtant teeth; higher up lanceolate, diſtantly ſerrate, (or entire) ſlightly hairy on the upper but more ſo on the lower ſurface, thoſe on the branches and at their baſe linear-lanceolate, entirely ſeſſile. Flowering heads numerous, on ſimple or branched ſlender peduncles. Outer ſcales of the calyx ſhort; inner longer, linear, with a green line along the back, and whitiſh membranaceous edges. Florets very ſmall. Seeds minute, crowned with a ſeſſile feather of few ſimple rays as long as the florets [f].—Florets in the centre yellow, in the circumference white, with a tinge of red [g]. The former are uſually four-cleft [h], but ſometimes only three-cleft [i], in number as far as ſixteen, of the latter there are ſometimes forty-ſix [k].

This came originally from North America; but now has the appearance of being indigenous in many parts of Europe: with us, it is not uncommon about London on cultivated grounds, and on rubbiſh. On St. Vincent's rocks, Briſtol. It flowers in auguſt. Petiver calls it white Golden-rod.

This being a naturaliſed plant, it would be curious to aſcertain when it firſt appeared among us in a wild ſtate. In Ray's ſynopſis it is ſaid to have been obſerved by Dr. Tancred Robinſon [l] (in 1667) ſays it is plentiful at Headington near Oxford, and in Yorkſhire. Peuver mentions its growing about London.

7. Root annual. Stem angular, firm, hirſute; branched at top. Leaves alternate, lanceolate, hirſute and ſoft, ſeſſile; the lower-ones tooth-gaſhed, the upper entire, narrower, and almoſt linear, towards the baſe waved, the midrib more prominent and hirſute. Flowers on the top of the ſtem, and at the extremities of the branches, one or two on a peduncle, and alternate; with pubeſcent calyxes: they are ſmaller than thoſe of *E. acre*, but larger than thoſe of the foregoing ſpecies [m].

Native of Buenos Aires in South America. Cultivated in the Eltham garden in 1732. It flowers in july and auguſt.

8. Root almoſt ſingle, but ſometimes ſubdivided, deſcending. Root-leaves lanceolate-wedge-form, ſubſeſſile, rounded at the end, with two, ſeldom three, diſtant ſerratures at top on each ſide. Stems erect or aſcending, often a ſpan high, filiform, pubeſcent, almoſt ſingle. Stem-leaves alternate, diſtant, lanceolate, acute, ſmall, nearly entire. Flowers ſubſolitary, terminating, peduncled, whitiſh. Common calyx ſingle, ſcarcely imbricate; ſcales membranaceous about the edge. Down appearing ſerrate when magnified, of a brown colour. Receptacle warted. Calyx ſpreading [n].

Sloane obſerves that the roots are ſmooth, white, no bigger than threads, and an inch and half long. Stem round, hoary, five or ſix inches high, having few leaves, placed without order, ſeſſile, with a narrow beginning, augmenting to a round end, about an inch long, rough, hoary, of a whitiſh green colour, very often having two or three notches. Flowers on the top of the ſtem, and from the axils, reſembling thoſe of Groundſel, compoſed of many ſmall yellow florets cloſe ſet together, encircled by many whitiſh, long, narrow ſemiflorets. Native of Jamaica.

9. Native of North America. Obſerved in Canada by Kalm. Perennial. It flowers from june to auguſt. Introduced about 1778 [o].

Loureiro thus deſcribes a Cochinchineſe plant under this name. Stem herbaceous, three feet high, erect, branched. Leaves ſinuate. Flowers yellow, panicled, terminating, oblong, many. The female florets in the ray very ſlender, erect. Receptacle naked. Down hairy. It agrees in the ſpecific character with this ſpecies, but it is doubtful whether they are the ſame ſpecies. The deſcription in Linnæus's ſpecies belongs to E. ægyptiacum.

10. Root perennial. Stem herbaceous, branched, a foot or more in height. Leaves alternate, ſharp, either entire, or with a few teeth about the edge. Flowers panicled. Leaflets of the calyx lanceolate, ſharp, equal, ſmooth, ſlightly keeled; the keel having a few hairs ſcattered over it. Corollets of the ray very numerous, purple; of the diſk yellow.—Native of Hudſon's Bay. Flowering in july and auguſt. Introduced in 1776, by Meſſrs. Gordon and Græffer [p].

11. Root annual. Stem ſimple, upright, a foot and half high, ſomewhat ſtreaked, aſh-coloured, pubeſcent, and ſomewhat viſcid. Leaves alternate, ſeſſile, ſcarcely half-ſtem-claſping, ſpatulate, or obovate-lanceolate, bluntiſh, ſubpubeſcent, marked with lines, having about five teeth, but entire at the baſe. Flowers panicled, terminating, four or five, peduncled, roundiſh, on purpliſh peduncles. Calyx roundiſh, with ſubulate, pubeſcent ſcales, patulous at the end. Corolla yellow: florets minute: thoſe in the ray naked and abundant. Style cloven, yellow, capillary, quickly diſappearing. Native of Sicily and Egypt [q].

12. Root annual, bitter. Stem upright, round, a foot high, ſimple, with a few upright hairs. Leaves

[a] Linn. Gouan, Villars. [b] Gen. prov. [c] Hort. kew. [d] Dillenius. [e] Woodw. Mſ. [f] Withering. [g] Haller. [h] Scopoli. [i] Pollich. [k] Murray. [l] Swartz. [m] Hort. kew. [n] Ibid. [o] Linn. mant.

alternate, half-ſtem-claſping, ſpathlate, level, with a few ſharpiſh ſerratures, the edge and keel ſubciliate. Flowers panicled. Calyx roundiſh, imbricate: ſcales lanceolate, naked, convex, cloſe, ſcarioſe about the edge, bluntiſh, not patulous with a ſubulate tip, as in *E. ægyptiacum*. The female corollets apetalous, more copious than the hermaphrodites. Stigma cloven, oblong. It approaches very near to E. ægyptiacum [r].

According to Gouan, the ſtem is ſmooth, very ſlightly ſtreaked, rough at the top, with whitiſh hairs preſſed cloſe. The root-leaves and lower ſtem-leaves are petioled, ovate, ciliate, an inch wide, near two inches in length, or as long as the petiole, very ſmooth, quite entire at the baſe, toothed from the middle to the tip; teeth large, equal, diſtant: middle ſtem-leaves ſeſſile or rather ſtem-claſping, lanceolate: upper ſtem-leaves, and thoſe on the branches, narrower, hirſute, quite entire. Peduncles axillary and terminating, bearing from three to ſix flowers, hoary, an inch and half long, corymbed: pedicels a line or two in length. Flowers the ſize of thoſe on E. tuberoſum, and globular. Calyx having the colour and appearance of Conyza chinenſis, but with the ſcales not at all ſquarroſe, fleſhy, green, membranaceous at the edge, and very ſmooth. Corollas whitiſh, with a white down.

Native of the Canary iſlands. It flowers in july and auguſt. Introduced in 1772, by Monſ. Richard [s].

13. *Root* perennial, or according to ſome biennial, fibrous, acrid. *Stems* ſix to eighteen inches high, upright, ſomewhat angular, hairy, often purple; in ſome ſcarce branched at all, in other plants very much ſo. *Leaves*, the lower ones oval or ſpatulate tapering to a footſtalk; the upper lanceolate, the uppermoſt linear; hairy on both ſurfaces, but moſt on the edges, which are entire and often waved. The upper part of the ſtem is divided into alternate branches, each bearing a ſingle flower. This never expands: it is externally purple, internally yellow, with a cavity in the middle. Scales of the calyx unequal, ſubulate, hairy, green. The corollets are uſually of three kinds; firſt, a few hermaphrodites in the middle of the diſk, with a five-cleft border, and ſhorter than the calyx: ſecondly, numerous females, on the ſides of the diſk, with a ſlender tube, the border obliquely truncate, the length of the calyx: thirdly, many (about forty) females in the ray; theſe are ligulate, upright, with two teeth on the edge, and longer than the calyx: the ſtyles of all are of the ſame height, and equal to the feather, which is ſeſſile, with yellow ſimple rays. In dry lofty paſtures, frequent, eſpecially in ſandy and calcareous ſoils. It is alſo often found on walls. Near London it is not a common plant; but it occurs frequently near Charlton-wood.

Johnſon in Gerarde ſays that he firſt obſerved it in company of Mr. George Bowles, Mr. John Bugs, and others, by Farmingham in Kent; and the laſt year (1635) Mr. William Broad found it growing at the blockhouſe at Graveſend.

It flowers from july to ſeptember.—The Germans take a decoction of it to attenuate viſcid phlegm.—Cows and goats refuſe it [t].

Our Engliſh botaniſts name it *blue-flowered* or *purple Fleabane*. Several ſpecies of this genus have this name of *Fleabane* in Engliſh; which tends (as Mr. Curtis very well obſerves) to confound this with the genus *Conyza*.

Gærtner remarks, that it has ſome affinity with Chryſocoma, and that Erigeron is a Chryſocoma with a diſcform ray.

14. This is like the foregoing, inſomuch that Haller doubts whether it be a diſtinct ſpecies, or only a variety. It has frequently a higher ſtem, but the height varies much in both; commonly one-flowered, ſeldom two-flowered. The flowers are larger; the ſemiflorets more numerous; the leaves longer; the feather denſe and whitiſh [u].

[r] Linn. mant. [s] Hort. kew.
[t] Woodw. Mſs. Curtis, Leers, Withering. [u] Krocker.

It varies with one, two and three flowers on a ſtalk, and ſometimes they are panicled: it varies alſo with a villoſe and ſmooth calyx [x]. The flowers in this come out from the middle and even the lower part of the ſtem; whereas in moſt of the ſpecies they branch out only from the upper part [y].

Native of Alpine paſtures. Found on Ben Lawers in Scotland by Mr. Dickſon in 1789. Perennial; flowering in july and auguſt.

Cultivated in 1759, by Mr. Miller [z].

Monſ. Villars has a ſpecies, which he names Erigeron atticum, from its reſemblance to Aſter atticus (Amellus Linn.) He deſcribes it as a foot high, and upright; the lower leaves large, ſpatulate, rough, three-nerved; the ſtem-leaves ſeſſile, lanceolate, gradually leſs and leſs: all hirſute, and a little viſcid. Flowers three, five or ſeven, in a terminating corymb. Peduncles naked, but villoſe and glutinoſe, as well as the calyx. Flowers blue, large, very wide, without any diviſion at the extremity of the ray. Seeds villoſe, terminated by an egret of white toothed hairs. Though it differs much from E. alpinum, yet that differs ſo much from itſelf, that it may be only a variety.

15. Root perennial. Stems a finger's length; ſcarcely three inches high, according to Haller; from a finger's length to a ſpan and more, as others ſay; very ſimple, ſtreaked, with wandering hairs ſcattered over them. Leaves few, lanceolate, almoſt ſmooth on the upper ſurface, but with ſpreading hairs ſcattered over the lower: the ſtem-leaves often ſublinear, the root-leaves oblong. The calyx conſiſts of very many, lanceolate ſcales, equal in length; the outer ones broader, ſpreading every way, with long hairs ſcattered over each ſurface. Ray white, length of the calyx, petals very numerous, linear, quite entire; ſtyle filiform, white, ſharp, bifid. Corollets of the diſk yellow, numerous, with yellow, bifid, obtuſe ſtyles. The flower is as large as in the foregoing ſpecies, thick, the ſcales covered with a white nap, lanceolate, broader: all the ſemiflorets ligulate, with no imperfect ones: ſometimes purple, according to Pontedera and Scheuchzer [a]. All the varieties with one and many flowers, with a ſmooth and hairy calyx, with blue and white flowers, make but one ſpecies, in the opinion of Allioni. Hence Scopoli has named this *E. polymorphum*. Monſ. Villars on the contrary, thinks that this bears little affinity to E. alpinum, or any other; from which it is eaſily diſtinguiſhed by the open ſcales of the calyx, loaded with long and wider hairs, be the plants ever ſo ſmall. He refers Oeder's figure to this ſpecies; but obſerves that he has never ſeen any ſpecimen ſo large as that repreſents.

Native of the European mountains from Lapland to Italy.

It flowers in auguſt and ſeptember. Introduced in 1775, by Drs. Pitcairn and Fothergill [b].

16. A very ſmall perennial plant, guarded with fading, dry leaves [c]. Native of Siberia.

17. Annual. Native of Virginia.

18. Annual. Stem ſimple, filiform, hairy, upright, a foot high. Leaves attenuated to the petioles, half-ſtem-claſping, obtuſe, upright, an inch in length. Flowers terminating. Feather ſimple, ferruginous. Native of Japan; flowering in june.

19. Stem filiform, branched, purpliſh, ſmooth. Leaves from each bud three or four, ſubſeſſile, ſharp, with ſetaceous teeth, villoſe on both ſides, half an inch in length. Flowers among the leaves, axillary ſolitary. Having ſeen only a ſingle flower, and that not open, Thunberg ſays he is not very certain about the genus [d].

20. Root perennial, bitten. Stem ſhort, woody. Branches ſimple, one-flowered. Leaves ſcattered, lanceolate, ſubpetioled, quite entire. Flowers yellow, like thoſe of *Aſter*, terminating, ſeſſile. Feather grey [e]. According to Gouan, the ſtem is from two

[x] Ger. prov. [y] Villars. [z] Hort. kew.

[c] Linn. ſpec. [d] Thunberg. [e] Linn. ſpec. & ſyſt.

inches

inches to a hand in height, covered with pellucid ſcattered hairs, thicker at the baſe. Branches few, terminating, divaricate. Lower leaves obovate-lanceolate or ſpatulate, often quite entire, not ſeldom toothletted. Peduncles rigid, rough with hairs, terminating, thickened at top; rather hiſpid, and frequently leafy. Flower twice as large as ſome of the other ſpecies. Calyx ſquarroſe, with the ſcales not unfrequently broader at the tip, and almoſt equal[f].—It is the link between this genus and *Aſter*. The varieties are from Gronovius[g].

Native of the South of France and Syria.

21. Root perennial, thick, fibrous, from which ariſe ſeveral upright, hairy ſtalks, near four feet high, putting out ſeveral ſide branches. Leaves ſeſſile, hairy, a quarter of an inch broad towards the end, where they are broadeſt, and diminiſhing gradually to their baſe; of a deep green on their upper ſide, and pale on their under, continuing all the year: they come out from the ſide of the ſtalk, and branches in cluſters from the ſame point, and without order on every ſide. The ſtem is terminated by ſeveral large corymbs of golden-coloured flowers. Theſe appear late in the autumn, continuing in beauty great part of the winter, fading in the ſpring, and are ſometimes ſucceeded by oval ſeeds, which ripen in England.

The ſtems generally decay the ſecond year, and are then ſupplied by new ones from the ſame root: the old ones remaining with their green hairy leaves in vigour, until the young ones are grown to a conſiderable height. Native of the Cape of Good Hope; and has been long cultivated in the curious European gardens[h].

It has a great reſemblance to *Inula fœtida*, but the flowers are floſculous[i].

Cultivated in 1722, in the botanic garden at Chelſea[k].

22. Annual. Stem herbaceous, a hand high, round, erect, hairy, branching very much. Branches from all the axils; the lower ones gradually longer, diffuſed, at top dichotomous, oppoſite. Leaves ſeſſile, half-ſtem-claſping, veined, not wrinkled, brittle, thinly haired; almoſt naked underneath, toothletted, ſharpiſh. Flowers ſolitary, the length of the peduncle, one-flowered, copious. Calyx cylindric, pubeſcent, with numerous, equal, ſubulate, approximating leaflets. Corollas yellow. Corollets of the diſk five-toothed; of the ray copious, but ſcarcely conſpicuous. Stigmas of the diſk erect, of the ray patulous. Native of the Eaſt-Indies[l].

23. A ſmall ſhrub, very much branched or panicled, leafy. Leaves ſubpetioled, ſcarcely half an inch long, naked. Flowers terminating, ſeſſile, ſeveral heaped together the length of a leaf. Calyx the ſize of a lentil ſeed. Female floſcets copious, apetalous. Feather ſcarce longer than the calyx, ſimple. Native of Mexico; obſerved there by Muris[m].

24. Stem herbaceous, upright, a foot high, ſomewhat hiſpid, ſimple. Leaves the length of a finger, ſomewhat toothed, roughiſh. Flowers terminating, ſubglomerate, yellow, the ſame ſize as in *E. acre*. Feather white. Native of the Cape of Good Hope[n].

25. Stem three feet high and more, round, ſtreaked, tomentoſe, red. Leaves ſeſſile, tomentoſe-hiſpid; the lower ones toothed, the upper ſerrate. Peduncles long, raceme-panicled, with one or two narrow-lanceolate leaves on them, generally entire. Calyx tomentoſe, with linear leaflets the length of the feather. Florets of the ray many, capillary, a little ſhorter than the feather; of the diſk funnel-form, few, the length of the feather, fertile. Feather ſimple, copious. Native of Sumatra[o].

26. Stem upright, ſimple, tomentoſe. Leaves petioled, with one or two long, ſharp teeth at the baſe on each ſide. Panicle diffuſed. Flowers the ſize of *Conyza cinerea*. Calyx imbricate, the outmoſt leaflets very ſhort, the inner a little longer than the florets: theſe ſeem to be yellow (as far as can be ſeen from a dry ſpecimen), and there are about twenty in the diſk: in the ray fewer, and thoſe filiform. Feather ſimple, reddiſh.—Native of Java. The two laſt were brought to Europe by Wennerberg[p].

27. Stem herbaceous, two feet high, erect, round. Leaves ſcattered. Flowers few, in a terminating erect panicle. Florets in the diſk yellow; in the ray ſtiff, quite entire, blue, many. Calyx ſubſquarroſe. Native of China near Canton[q].

28. This is an annual plant, native of Jamaica and Hiſpaniola[r].

29. Stem erect ſtriated pubeſcent, tomentoſe at top, branches woody. Leaves quite entire. Pedicels capillary, with a pair of minute leaflets towards the tip. Calyxes villoſe; ſcales briſtle-ſhaped, ſhorter than the down. Corollas of the ray naked. Native of Arabia.

30. This is a ſhrub with tomentoſe branches. Leaves ſeſſile, approximating, gradually narrowed at the baſe, ſharpiſh, a little rolled back at the edge, ſometimes having a ſingle tooth or two. Corymbs terminating, many-flowered. Calyx ſubvilloſe, with linear leaflets. Corollets of the ray naked. Down ferruginous, longer than the calyx. Native of Arabia Felix[s].]

PROPAGATION AND CULTURE.

1. This plant is propagated by ſeeds, which, if ſown in autumn, will more certainly ſucceed than thoſe which are ſown in the ſpring. When the plants come up, they ſhould be thinned if they are too cloſe, and kept clean from weeds till autumn, when they ſhould be tranſplanted where they are to remain. They delight in a dry ſoil, and a ſunny expoſure. The ſecond year the plants will flower and perfect their ſeeds, but the roots will continue ſeveral years, and annually produce their flowers and ſeeds.

6, 7, 13, 14. Are preſerved in botanic gardens for the ſake of variety, but are ſeldom admitted into gardens for pleaſure. The fourteenth ſort is a perennial plant, which grows naturally on the Alps, and may be propagated by ſeeds in the ſame manner as the firſt ſort, but ſhould have a ſhady ſituation, and a moiſt ſoil.

The others are annual plants, which, if once admitted into a garden, and ſuffered to ſcatter their ſeeds, will become very troubleſome weeds there. They will help very well to cover rubbiſh or rock-work.

21. This is too tender to thrive in the open air in this country, ſo the plants ſhould be kept in pots; and if in the winter they are placed in a common frame, where they may have a large ſhare of free air in mild weather, and ſcreened from hard froſts, they will thrive better than with tender treatment. It is eaſily propagated by cuttings, which, if planted in May, will readily put out roots, and the young plants will flower the autumn following.

DESCRIPTIONS, *&c.*

[Leaves moſtly alternate; flowers either axillary or with one bracte to each, in a terminating ſpike [a].

1. Root perennial. The root-leaves form a thick tuft cloſe to the ground, they are all linear-ſpatulate, pubeſcent, with a few ſerratures at the end on both ſides. Leaves on the ſtem alternate. Stems many, very ſimple, a hand high, round, pubeſcent, upright; the ſide ones barren and decumbent. Flowers alternate, ſeparated by leaves like thoſe on the ſtem, but ſmaller, and forming an upright, ſimple raceme. Calyx bell-ſhaped, five-parted, permanent. Corolla funnel-ſhaped. Stigma with two ſmall roundiſh oppoſite ears [b]. Capſule ſmall, grooved on each ſide, the valves when ripe biſid to the middle. Partition doubled, formed by the edges of the valves bent in. Receptacle oblong, compreſſed a little, not faſtened to the partition. Seeds ovate, ferruginous, rugged with obſcure crowded tubercles [c].]

The leaves are about half an inch long, and one-eighth of an inch broad, of a dark green. The flower-ſtalk is ſcarce two inches big; the flowers are in a looſe raceme, and purple. They appear in may, or earlier, and ſometimes are ſucceeded by ripe ſeeds in july.

[It is a deſirable little plant for the decoration of rock-work, growing in cloſe tufts, and producing its numerous lively purple flowers during moſt of the ſummer months [d].

Native of Germany, of the Swiſs Alps, of the Pyrenees, and the South of France.—Cultivated in 1759, by Mr. Miller [e].

2. Stem herbaceous, branched, a ſpan long, declined. Leaves oppoſite, ſeſſile, obtuſe. Flowers ſolitary, in the axils of the leaves, purple, ſlender.

Native of Africa; communicated by Burmann.

β. Stem herbaceous, ſimple, a ſpan high, erect. Leaves oppoſite, ſeſſile, acute. Flowers ſolitary, from the axils of the upper leaves, purple, twice as large as in the other.—Native of Africa; communicated by Gronovius [f].

3. Perennial. Stem erect, round, pubeſcent, two feet high. Leaves alternate, except the lower ones, which are oppoſite, ſeſſile, linear, toothed, remote, pubeſcent. Spike terminating, oblong, imbricate with broader, ovate-lanceolate, toothed bractes. Calyx ſeſſile, the length of the bractes, five-toothed, two-parted, upright, obtuſe, broader at bottom. Corolla yellow, ſmelling very ſweet; tube filiform, three times as long as the calyx; the five lobes of the border are cloven half way, obovate and equal: two of the anthers at the mouth of the tube, and two below the jaws. Style filiform the length of the tube [g].

Native of the Cape of Good Hope.

4. Stem ſimple: leaves alternate, from the axils; ſpike long with the flowers remote; corollas tomentoſe on the outſide, of a dark colour, fragrant at night.

Native of the Cape of Good Hope.

This was introduced in 1776, by Meſſrs. Kennedy and Lee [h].

5. Native of Peru. Said alſo to be found at the Cape.

[a] Juſſieu. [b] Linn. ſyſt. [c] Gærtner. [d] Curtis. [e] Hort. kew. [f] Linn. cliff. [g] Linn. mant. [h] Hort. kew.

6. There

6. There is no deſcription of this or of the others.

7. The flowers are of a dull colour, but ſweet[1].

All theſe are natives of the Cape.

8. See Buchnera canadenſis and Verbena Aubletia.]

9. Stems trailing, about ſix inches long. Leaves ſmall, oval, placed on every ſide, very white and woolly. At the joints juſt above the leaves come out the flowers, ſitting very cloſe to the ſtems: they are white, and are ſucceeded by round capſules.—This plant has great reſemblance at a diſtance to Sea Cudweed. It was ſent to Mr. Miller by Dr. Houſtoun from La Vera Cruz.

10. Stem upright, two feet high: towards the top two ſmaller branches, oppoſite and erect; theſe and the middle ſtalk are terminated by looſe ſpikes of purple flowers, ſucceeded by oval capſules. Diſcovered by Dr. Houſtoun at the ſame place.

11. Stems ſhrubby, about four feet high, dividing into ſeveral ſmall hairy branches. Leaves deeply ſerrate, and on pretty long foot-ſtalks. Flowers ſingle, or two and three at a joint, ſeſſile, white, ſucceeded by round capſules.

12. Stems many, ſmooth, branching out very much on every ſide, about ſeven or eight inches long, and garniſhed with ſmall leaves. Flowers ſeſſile, white, making but little appearance, and ſucceeded by round capſules.

13. Stems ſeveral trailing ſix inches long, dividing into many ſmaller branches. Leaves oppoſite, ovate. Flowers bright yellow, on long ſlender pedunculs, ſucceeded by oval capſules.

[This is a ſpecies of Lindernia, according to Swartz, and a native of Hiſpaniola. See *Lindernia*.]

PROPAGATION AND CULTURE.

1. This is propagated by parting the roots in autumn; they muſt have a ſhady ſituation and a loamy ſoil without dung, for in rich earth they are ſubject to rot.

[2. to 7. The Cape ſorts muſt be kept in the greenhouſe, dry ſtove, or glaſs-caſe, and may be increaſed by cuttings.

8, &c. Thoſe from South America muſt be placed in the bark-ſtove.] The eleventh being a ſhrubby plant will continue ſeveral years, but the others are annual. They are propagated by ſeeds, ſown in pots filled with light earth, and plunged into a moderate hot-bed, where ſometimes they will come up in five or ſix weeks; but they frequently do not vegetate till the following ſpring, eſpecially when the ſeeds have been kept long. When the plants are fit to remove, they ſhould be each planted in a ſeparate ſmall pot filled with light earth, not too rich with dung, and then plunged into the bark-pit. When they have taken new root, treat them as other plants from the ſame countries, by admitting proper air when the weather is warm, and frequently refreſhing them with water; with this management the annual ſorts will flower in july and auguſt, and often ripen their ſeeds in autumn, if they be brought forward early in the ſpring.

The ſhrubby ſort muſt alſo frequently be refreſhed with water in winter, but not in large quantities, nor in very cold weather: the plants will flower and perfect their ſeeds the ſecond year.

DESCRIPTIONS, &c.

1. Linneus ſays he could not diſcern the floſcules in Piſo's herbarium, which is in the poſſeſſion of Burmann.—Native of Braſil.

2. Native of the Eaſt Indies.

3. The leaflets ſurrounding the head inſtead of an univerſal calyx, are orbiculate; not as in the foregoing narrow[2].

4. This is a ſmall annual herb, tufted and bent back, in a ring. Culm very ſlender, four inches high, almoſt naked. Leaves ſhort few, vaniſhing as they grow old. Heads terminating ſmall oblong ſub-acute[3].

Flowers aggregate, male and female in the ſame common globular, chaffy receptacle. Calyx none. The male flowers have three petals to the corolla, ſomewhat hirſute on the outſide, and ſix ſtamens: the females have ſix petals, and reſemble the males: they have a roundiſh three-cornered germ and three ſtyles. The capſule is membranaceous, diaphanous, pedicelled, three-celled, with one ſmall, compreſſed, ovate ſmooth ſeed, with a little beak at top, and of a reddiſh colour, in each cell: it ſcarcely ever opens ſpontaneouſly[4]. According to Loureiro, the ſeeds are ſubtriquetrous.

The leaves are altogether ſetaceous. A membranaceous ſheath like a ſpathe includes the culm at the baſe. The roots are diſperſed in the water[5].

Theſe are natives of the Eaſt Indies, and this of Cochinchina.

5. Leaves two, ſubulate, flat, channelled, jointed, Flowers in a head, with male flowers in the diſk, and female in the circumference.

[1] Linn. ſuppl.

[2] Linn. zeyl. [3] Loureiro. [4] Gærtner. [5] Linn. zeyl.

The character of the genus remains to be examined in the other species. Hope has very well described this. The remaining species muſt be ſeen before the character can be corrected[a].

Native of North America in the ſwamps.

6. This is an annual herb, with an upright naked four-cornered culm, eight inches high. Leaves ſhort, ſmooth, few. Head of flowers whitiſh, flattiſh at the baſe, with roundiſh ſcales, attenuated at bottom, one flowered, cloſed. Petals two, ſubconcave, blunt at the tip, toothed. Seeds three ovate. Common every where in Cochinchina[b].]

ERIOCEPHALUS. (*From* ἔριον, *wool, and* κεφαλὴ, *a head.*)

DESCRIPTIONS, &c.

1. This plant has a ſhrubby ſtalk from four to ſix feet high, putting out many ſide branches the whole length. Leaves woolly, coming out in cluſters, ſome taper and entire, others divided into three or five parts, which ſpread open like a hand; they have a ſtrong ſmell when bruiſed approaching to that of Lavender Cotton, but not quite ſo rank. The flowers are produced in ſmall cluſters at the ends of the branches, and ſtand ereſt. The female florets which compoſe the ray form a hollow, in the middle of which the hermaphrodite florets forming the diſk are ſituated; the border is white, with a little reddiſh caſt on the inſide, and the diſk is of a purpliſh colour. The flowers appear in autumn, but do not produce ſeeds in this country.

[Cultivated in 1732, by James Sherard, M. D. at Eltham. It flowers from january to march[c].

2. This has the ſtature and appearance of *E. africanus*, but all the leaves are undivided: flowers on peduncels ſhorter than the calyx: outer ſcales of the calyx four, ovate, ſubtomentoſe, with a very ſoft wool from the boſom of them[d].

[a] Linn. ſyſt. [b] Loureiro. [c] Hort. kew. [d] Linn. amœn.

Gærtner affirms, that there is no veſtige whatever of the outer calyx in this ſpecies. The receptacle is flat, and has a copious ſilky down on it, of a whitiſh ſtraw-colour, and longer than the florets. Seeds of the females oblong, narrowed downwards, compreſſed three-ſided, hairy or ſparingly woolly, but otherwiſe deſtitute of all down.

This was cultivated by Mr. Miller in 1758. It flowers in march and april[1].

Both are natives of the Cape of Good Hope.]

PROPAGATION AND CULTURE.

1. This plant is propagated by cuttings, which may be planted any time from may to the middle of auguſt, for if they are planted later in the ſeaſon, there will not be time for them to get good root before the winter; theſe cuttings ſhould be planted in ſmall pots filled with light earth, and plunged into a very moderate hot-bed, where they ſhould be ſhaded from the ſun till they have taken root; theſe muſt be refreſhed with water two or three times a week, but they ſhould not have too much at each time, for much moiſture is very hurtful to theſe plants. When the cuttings have taken root, they ſhould be gradually inured to the open air, to prevent their ſhoots from being drawn up weak; afterward they ſhould be removed into the open air, and placed in a ſheltered ſituation, where they may remain till october, when they muſt be removed into an airy glaſs-caſe, that they may have as much ſun as poſſible, and enjoy the free air in mild weather, but ſecured from froſt and damp air, either of which will ſoon deſtroy them. During the winter they muſt be ſparingly watered, for the reaſon before given; but, in the ſummer, when the plants are placed in the open air, they will require to be frequently refreſhed with water in hot weather.

Theſe plants retaining their leaves all the year, add to the variety of exotics in the winter ſeaſon.

Culms naked three-cornered, ſpike ſhorter than the down.

DESCRIPTIONS, *&c.*

Root perennial. Culm cylindric. Leaves linear. Allied to the graſſes.

1. Root-leaves obſcurely three-cornered, ſharp, ſtreaked on two ſides; convex on one ſide, flat on two ſides. Scape twice as long as the leaves, flattiſh on one ſide ſtreaked. Stem-leaves awnleſs, ſheathing; ſheath ſwelling a little; the uppermoſt purple at the baſe. Spike ovate, imbricate on every ſide with membranaceous brown ſcales; the lower ones barren, the upper ones woolly-fruit-bearing [a].

It differs very obviouſly from the third ſpecies: the root being not creeping but more matted; the leaves much finer, and conſequently more apt to grow in tufts; the ſheath of the upper ſtem-leaf in particular is remarkably inflated, and it never produces more than one ſpike which is upright [b].

Native of bogs in cold barren ſituations, in many parts of Europe. Not ſo general with us, but in ſome places equally common. Near London on Shirley-common by Croydon; near Lynn; Birmingham-heath. Frequent in all the northern counties; Elſemere-meers in Shropſhire; Pillimoſs in Lancaſhire; Bawſey-bottom near Lynn, Norfolk.

It flowers ſomewhat earlier than the anguſtifolium, but produces its down about the ſame time [c].

Sheep are very fond of it, whence in Weſtmoreland they call it *Moſs-crops* [d]. As they do alſo the third ſpecies, not diſtinguiſhing them.—Ray calls it *Hare's-tail Roſh.*

2. Linneus confounds this and the next ſpecies together; and refers to the firſt figure of Vaillant only as a variety of his polyſtachyon: but if he had ever ſeen both plants together he would doubtleſs have made them diſtinct ſpecies. The following particulars may ſerve to ſhow in what our plant differs from E. polyſtachyon. 1. The root of that is not creeping. 2. The culm is very erect. 3. The leaves are ſhort and flat. 4. The ſpikes are many, upon ſlender foot-ſtalks, and pendulous. 5. The involucre is ſhorter than the ſpike [e]. Bogs in ſeveral counties of England, and very common in Scotland.

3. Our Engliſh writers have followed Linneus in confounding this with the foregoing, till Mr. Dickſon diſtinguiſhed them.

Stem, from nine inches to a foot or more in height, upright, ſmooth, with two joints projecting a little, covered throughout its whole length with the ſheaths of the leaves. Thoſe next the root are of a cheſtnut colour, ſhort, lanceolate, ſtreaked, marked with tranſverſe lines, which give them a reticulated appearance: the ſucceeding leaves at their baſe cloſely embracing the ſtalk, from two to three lines in breadth, about ſeven inches or more in length, gradually tapering to the extremity, convex on one ſide, concave on the other, and ſmooth; the uppermoſt leaves flatter, much ſhorter, and manifeſtly keeled; ſheaths nearly of an equal thickneſs throughout, where a leaf goes off more looſely connected, and marked with a fiſſure filled by a membrane. Floral-leaves three or four, of unequal lengths, forming ſheaths at bottom, terminate the ſtalk, from the axils of which the ſpikelets proceed. Theſe are from to ſeven (generally about three), ovate, firſt upright, afterwards pendulous [f].

Gærtner deſcribes the fruit as a ſmall coriaceous-cruſtaceous nut, of an obovate form, three-cornered, ſmooth or obſcurely ſtreaked, of a reddiſh cheſtnut colour, one-celled, valveleſs, clothed at the baſe with a white ſilky down, quite ſimple, and twelve times as long as the nut. Seed ſingle, ſubelliptic, obſcurely three-cornered, pale.

In Germany, and the more northern parts of Europe, the down has been manufactured into various articles of dreſs, paper, and wicks for candles. In ſome parts of Sweden the peaſants ſtuff their pillows with it, whence it is called Poor-man's Pillow: but it becomes brittle when quite dry.

Early in the ſpring cattle crop the leaves, before the graſſes are ſufficiently grown.

It is common on moors and boggy ground; inſomuch that they are often white all over with it in June and July, when it is in ſeed. It flowers in April and may.

4. Culms compreſſed. Spike compact, leafy, large, brown or gold-coloured.—Native of Virginia.

5. This has altogether the ſtature of *Cyperus*, but the ſpikelet of *Scirpus*, except that the ſeeds as they ripen produce a dun-coloured or teſtaceous cotton, ſcarcely longer than the ſpikelets [g],—Native of North America.

6. Thick tufts of culms and leaves riſe from the root. Culms without knots very ſlender, three-cornered, rough in drawing the fingers from the top downwards,

[a] Linn. ſuec. [b] Curtis. [c] Ibid. [d] Ray ſyn. [e] Dickſon. [f] Curtis [g] Lin. ſpec.

downwards, a hand or half a foot in height, involved at the base in sheaths gradually larger, acuminate, the lower shorter and brown, the rest green. Leaves very slender, almost setaceous, three-cornered, rough backwards, almost of the same length with the culm. Spikelet erect, having no sheaths, the least of all the species, swelling, only one or two lines in length, pale yellowish brown, with white hairs much longer than the spikelet, which is made up of lanceolate, acuminate, imbricate glumes, the lowest longer and broader than the rest, divided by a nerve that stands out and is extended into a point. Seed very small, yellowish[k].

Native of the mountains of Lapland, Sweden, Denmark, Silesia, Carniola, Switzerland. Flowering in june and july.—It was found by Mr. Brown and Mr. Donn, in a moss about three miles east of Forfar, in the shire of Angus, Scotland, 1791. A specimen of it from this place was presented to the Linnean Society by Mr. Teasdale, april the 3d, 1792.

PROPAGATION AND CULTURE.

These being bog plants, are seldom preserved in gardens. They may however be planted in pots filled with bog earth, set in pans wherein water is kept constantly; or by the side of ponds or other waters.

Leaves obovate; flowers axillary, males cymed, hermaphrodites solitary.

DESCRIPTIONS, *&c.*

1. This is an upright elegant branching tree, fifteen feet in height. Leaves subovate, blunt with a small point, shining, quite entire, deep green, paler underneath, petioled, three inches long. Racemes compound, corymbed, axillary, opposite. Flowers numerous, caducous, with white petals, mostly six-

[k] Krocker.

stamened with a six-cleft calyx and corolla, smelling exactly like the common Syringa. Berries small and purple, (black, *Swartz*) Seeds about nine, but uncertain in their number: (in each cell one, rufescent, *Gærtner*). Perhaps both the species of Brown are but varieties of this.

Native of Jamaica, Martinico, *&c.*[l]

Jacquin describes another, which is a native of Curaçao, and probably a variety of this arising from its growing in the clefts of rocks, where there is no earth. It is a shrub, two feet high, with procumbent diffused branches; the leaves are thicker and numerous; the berry and flowers smaller; the former entirely void of scent, the latter whitish or very seldom purple.

According to Swartz, it varies with large ovate leaves and all the parts larger.

The berry, as Gærtner observes, may with Jacquin be considered as one-celled.

2. Native of the Society Isles. The variety has narrower leaves[k].

Knoxia. *Brown. jam.* 140. 1.

Thymelæa. *Sloan. jam.* 2. 93. *t.* 189. *f.* 1, 2.

DESCRIPTION, *&c.*

Branches four-cornered, wand-like, jointed, ash-coloured, leafless; branches alternate, two inches long. Leaves on the branchlets opposite, sessile, an inch and half long, lanceolate, attenuate to both ends, veinless, obscurely three-nerved or five-nerved, very smooth on both sides, shining, quite entire, mucronate, cusped. Stipules surrounding the branch, truncate, ciliate. Flowers axillary, opposite, sessile. Calyx deeply four-parted, with lanceolate cusped segments. Tube of the corolla slender, longer than the calyx; segments of the border linear obtuse. Stamens the length of the corolla. Stigma truncate.

It varies with broader and narrower leaves[l].

Native of Jamaica, frequent near the shore in the parish of St. George, running three or four feet or more along the ground, throwing out a few spreading branches as it creeps along. The leaves are oblong, pointed and stiff; the flowers few, single, at the axils of the upper leaves[m].

Browne named this plant Knoxia, as I presume, from Knox, who resided many years in the Island of Ceylon, and published an account of it.]

ERODIUM. (ἐρωδιὸς *is the name of the Crane in Aristotle, whence this genus is so called on account of the long beak to the fruit.*)

DESCRIPTIONS, &c.

The genus Geranium was first separated into three genera by Monsieur L'Heritier. Of these this of Erodium is one, Pelargonium is a second, and the third retains the old name of Geranium. The division is convenient on account of the prodigious number of species, but they must still be considered as making only one natural genus.

1. This seems to differ from the next species in being caulescent, and in having the segments of the leaves linear and subvillose, not oblong and silky, as in that. Found in Armenia by Tournefort, and on mount Olympus by John Sibthorp, M. D.

2. This is very distinguishable by its yellow flowers. Found on mount Parnassus by John Sibthorp, M. D.

3. It may be doubted whether this be any thing more than a variety of the preceding. It differs however in having the flowers flesh-coloured marked with lines, the leaves smaller and less cut, the scapes leafless and radical; whereas E. chrysanthum becomes branched when in flower. Found on mount Libanus by Billardiere.

4. The plant is wholly covered with frequent short villose hairs, whence it has the appearance of being dusty. It is certainly allied to the first and second species, from which it differs in its dusty habit, in having the leaves decompoundedly laciniate not interruptedly bipinnate, the flowers more numerous in the umbel, and the fruits only one-third of the length. Found by Louiche Desfontaines in the kingdom of Tunis.

5. In appearance this resembles Pelargonium myrrhifolium. It differs from the three next, in having thick leaves, pinnatifid not interruptedly pinnate, bractes larger, and roundish not lanceolate, the herb caulescent, and the root more slender not thick[a].

Found in the island of Cyprus by John Sibthorp, M. D. and introduced here in 1788. It flowers in april and may[b].

6. All the leaves are heaped about the root; they are hoary with hairs, the whole forming a triangle; pinnas commonly three or four pairs, the outmost smaller: pinnules pinnatifid, with the leaflets acute, bifid, trifid or entire; between these are leaflets which are entire. Petioles twice or three times the length of the leaves, hoary with shining hairs. Scape scarcely three inches high, round, hispid with pellucid hairs, bearing from one to six flowers. Pedicels equal, half an inch long, pubescent. Calyxes large, striated, very hirsute; leaflets blunt, membranaceous at the edge, ending in a short awn. Corolla large, blue-purple or red. Seeds oblong, with the beaks only double the length of the calyxes[c].

Lobel reports it to be abominably fetid. L'Heritier says it is singular in having a very strong nauseous smell like some of the class Syngenesia; and according to Gouan, it has a strong smell, but neither nauseous nor musky.

Native of the country about Montpellier. It seems to have been cultivated here in the time of Parkinson.

7. This is allied to the preceding. The herb is entirely the same. The leaves, which are very much alike, are more finely laciniated and more slender in this; they are subcaulescent in E. fœtidum, not paler, as in this. E. macradenum has also a turpentine or musky smell. Petals roundish equal

[a] L'Heritier. [b] Hort. kew. [c] Gouan.

concolor purpliſh fleſh-coloured, marked with deeper lines, with villoſe claws in that; in this they are ovate, nearly equal, the two upper ones ſcarcely larger but marked with dark violet-coloured veins, and the claws are naked. Filaments erect in that, reclining after flowering time in this. Glands very large globular broader than long in E. macrademum; ſubbilobed in E. fœtidum.

Native of Spain.

8. This is very nearly allied to the two preceding and to E. romanum. In the laſt the plant is larger and ſubſtrigoſe, the leaves ſimply not interruptedly pinnate, and the leaflets gaſh-pinnatifid: in E. fœtidum and macrademum the plant is hirſute, the leaves interruptedly bipinnate, the leaflets pinnatifid-laciniate: in this the habit of the plant is hoary and ſilky, on account of the upper ſurface of the leaves being ſo, the peduncles are few-flowered, and the leaves interruptedly bipinnatifid.

Found in Monſerrat in Catalonia by Brouſſonet, Sibthorp and Pourret.

9. This has the habit of the three laſt, from which however it differs in having pinnatifid leaves, not interruptedly ſo, and elongated ſtems.

Found on the ſandy coaſts of Barbary by Poiret [a].

10. Root perennial, running very deep into the ground. Lower leaves ſmooth and on very long footſtalks. Stems a foot and half high, with leaves of the ſame form, but ſmaller and oppoſite. Flowers purple, many together on very long peduncles. [The calyx is awned: the petals are about twice as large, and entire.

Native of Italy [b].]

The ſeeds were ſent to Mr. Miller by Micheli.—It flowers here in June, but the ſeeds do not ripen in England.

11. This has a pretty thick tuberous root. Stems irregular, branching, diffuſed, ſomewhat woody, and having ſwelling joints; at each of theſe is one leaf, oppoſite to which comes out the peduncle: the peduncles on the lower part of the ſtem are very long and naked, but thoſe which terminate the branches are ſhorter, and have one or two ſmall leaves at their baſe; the flowers are in ſmall bunches, and continue in ſucceſſion moſt part of the ſummer. [L'Heritier doubts whether it be ſpecifically diſtinct from E. cicutarium.

Native of Italy, about *Rome*, on the Pyrenees, alſo of Provence.—It was cultivated in the botanic garden at Chelſea in 1724 [c].

12. Root annual. Stems ſeveral, thickiſh, round, hirſute, procumbent and branched. Pinnas of the leaves ſlightly hairy; pinnules ſharply indented. Stipules at the baſe of the leaves membranaceous, whitiſh, acutely ovate, the uppermoſt entire, the lowermoſt generally divided into two. Peduncles axillary, alternate, hirſute, the length of the leaves. Flowers in an umbel, from three to ſix, of a roſe-colour. Calycine leaflets ovate, ſtriated, hirſute, ending in a fine point. Petals ſubovate, flat, nearly equal, hairy at bottom, ſomewhat longer than the calyx. Anthers deep purple. Neſtareous glands brown. Germ villoſe: ſtyle awl-ſhaped, grooved: ſtigmas purple. Seeds brown: aril hirſute: awn long, hairy [d].

This ſpecies varies extremely, from nearly ſmooth to very hairy, and from very large and branched, with a many-flowered umbel, to ſmall and nearly ſimple, with few flowers [e].

β. Geranium pimpinellæ folio of Dillenius is a remarkable variety; the petals irregular, the two upper ſhorter, rounder, and marked with a greeniſh ſpot at the baſe [f].

The wings of the leaves have deeper winged clefts, and the pinnules are nearly linear, rarely jagged. Sometimes only one petal is ſpotted, ſometimes three or four, nay even all five; the ſpotted ones are always broad and ſhort, and in the laſt caſe the corolla became regular [g].

The common ſort [h] is found all over Europe, in Africa, Aſia, North America, and the iſland of Madeira. The laſt-mentioned variety has been found in England near Hackney, and in ſeveral parts of Suffolk.

13. This is very like the preceding, but has an ambroſial or muſky ſcent; the whole plant is covered with hairs, which are glutinous, particularly thoſe of the calyx. All the parts are larger; the ſtem is ſwollen and crooked at the joints. The wings are fewer in the leaves, ovate, ſometimes only ſerrate or jagged, rarely pinnatifid. Peduncles thickly ſet with fine white hairs, ending in pellucid globules, with from four to ten flowers, forming a roundiſh head. Corolla red or purple [i]. Annual.

Native of England, France, Switzerland, the Cape of Good Hope, Syria, Barbary, Peru. With us about Batterſea, Streatham, &c. near London, near Briſtol, Stourbridge; in Weſtmoreland and Yorkſhire.

14. This ſeems to differ from the preceding in having a perennial root, and bipinnate leaves; but it is perhaps no more than a variety.

Found on rocks near Algiers by Deſfontaines [k].]

15. This is an annual plant with very broad leaves, cut on their ſides regularly and crenate. Flowers on long axillary peduncles. Petals entire and blue. Beaks of the fruit remarkably large. [The ſtem is quite ſmooth, whereas in the next ſpecies it is rough with hairs or ſtrigoſe.

Native of Spain, Sicily, Candia, Cyprus, Syria [l]. Cultivated in 1596 by Gerarde [m].]

16. This alſo is an annual plant, which has ſeveral proſtrate ſtems near a foot long. Peduncles axillary, three inches long. Flowers pale blue. Beaks of the fruit very long, but by no means ſo long or large as thoſe of the preceding.

[Native of the South of Europe, Barbary, Syria, Cyprus, Madeira.—Cultivated in the botanic garden at Chelſea in 1724 [n].

β. In this variety the whole plant is rough with hairs. It is a native of Spain, Portugal and Italy, on ſandy coaſts.

17. Stem grooved, branched, more than a foot high. Leaves oppoſite, longer than the petioles, divided almoſt to the petiole, into three pinnated ſegments; the pinnules linear with a point. Stipules ſcarioſe, broadiſh. Peduncles alternately axillary, longer than the leaf. Involucre ſcarioſe, multifid: rays ſix or more, half an inch long. Calyx ovate, ten-ſtriaked; leaflets ovate, awned. Corolla a little larger, very pale blue, with equal petals. Fruit rufeſcent, with a beak two inches long [o].

Native of Portugal.

18. The involucre is compoſed of two oppoſite, membranaceous, largiſh bractes, that are very conſpicuous, and give it the ſignificant trivial name.

Native of Portugal, Gibraltar, Algiers, Tunis, Candia, and Cyprus. Annual [p].

19. Calyxes without any awns. Leaves a little reſembling thoſe of A. Ceterach.—Found by Deſfontaines in the kingdom of Tunis [q].

20. The ſtem is ſcaly at the baſe with membranaceous ſtipules, larger than in any other ſpecies.—Found by Desfontaines on rocks in Barbary [r].

21. This has the habit of Potentilla, with a ſlender, ſmooth, hard ſtem, inclining to ſhrubbineſs. The leaves are on very long petioles, heart-ſhaped, roundiſh, undivided, ſmall. Stipules lanceolate, very ſharp. Flowers red, fleſh-coloured, or ſcarlet with a paler diſk [s].

Native of the Cape of Good Hope. Introduced in 1787, by Maſſon [t].

22. This is an annual plant, with the lower leaves heart-ſhaped and three-lobed. Branches inclining to the ground, and ſpreading a foot and half each way. The peduncles are placed on the ſide of theſe, and ſuſtain many bright-red flowers. The fruits have long beaks.

[a] L'Heritier. [b] Ibid. [c] Hort. kew. [d] Curtis. [e] Woodw. Mſs. [f] L'Heritier. [g] Woodw. Mſs.

[h] Ibid. and With. [i] L'Heritier. [k] Ibid. [l] Hort. kew. [m] Ibid. [n] Cavanilles. [o] L'Heritier. [p] Ibid. [q] Ibid. [r] Ibid and Cavan. [s] Hort. kew.

[Native of the South of Europe, Madeira, Barbary, Syria, the Iſlands of the Archipelago and in Peru. Cultivated in 1596, by Gerarde [r].

β. The variety is native of the Iſland of Chio.

23. This has the habit of the preceding; from which however it ſeems to differ in its ſtipulation, and in the hirſuteneſs of the filaments, which are ſmooth in malacoides and chium.—Found in Barbary by Poiret [s].

24. Monſ. L'Heritier doubts whether an older plant of this might not prove to be the ſame with E. diphyllum or lacerum. Native of Sicily.]

25. This is an annual plant, [with leaves very like thoſe of E. malacoides, but ſmooth. Stem extremely ſimple, very ſhort. Peduncles from three to five-flowered. Corolla purple or pale blue, with a dark trifid line at the baſe [t]. It is eaſily known by the gray or glaucous colour of the leaves, and the very long feathered beaks to the fruit.

Native of Egypt [t]. Cultivated here in 1732, by James Sherard, M. D. [c]

26. This is very nearly allied to the preceding, but the herb is ſilky and hoary, not naked and glaucous, as in that. The leaves approach more to the heart ſhape, whereas in glaucophyllum they are oblong. The calyxes have alſo longer awns. The flowers are violet-coloured with a very dark violet diſk, and are extremely ſweet ſcented.

Found by Shaw and Desfontaines in Barbary [t].

27. Stems branched, lying cloſe to the ground. Root-leaves on long petioles, ſpreading in a circle on the ground, hairy, variouſly cut and jagged, ſometimes nearly lobed; ſtem-leaves ſimilar. Peduncles ſhorter than the leaves. Flowers one to three, pale red, ſmall. Beaks of the fruit very ſmall, not exceeding half an inch in length [u].

Native of England and Holland, on the coaſt, Norfolk and Cornwall. Alſo on ſandy commons in Worceſterſhire.

28. Leaves radical, on very large petioles, numerous, orbiculate-heart-ſhaped, ſhining, much ſhorter than the petioles. Scapes a little longer than the petioles, with oppoſite bractes. Petals white, quite entire, oblong, with villoſe claws, between which are green fleſhy obcordate glands [r].

Native of Minorca and Corſica.—It has been known many years to the nurſery-men by the name G. Reichardi, in compliment to a French gentleman, who firſt diſcovered it in the iſland of Minorca [x].

PROPAGATION AND CULTURE.

See GERANIUM.

EROTEUM. (*So named by Swartz, I preſume from* Ερως.)

Lin. gen. Schreb. n. 1757. 2. *p.* 807. *Swartz prodr.* 85.

Claſſ. 13. 1. Polyandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* five-leaved; *leaflets* ovate, concave, incumbent, permanent.

COR. *Petals* five, ovate-roundiſh, concave, entire, ſpreading.

STAM. *Filaments* numerous (thirty), ſhorter than the petals, erect, filiform, placed on the receptacle. *Anthers* roundiſh, minute.

PIST. *Germ* ovate, pubeſcent, ſuperior. *Style* erect, generally longer than the ſtamens, awl-ſhaped, trifid at the tip, permanent. *Stigmas* obtuſe, ſimple, reflex.

PER. *Berry* roundiſh, juiceleſs, acuminate with the permanent ſtyle, ſmooth, three-celled.

SEEDS in threes or fours, oblong, compreſſed a little.

OBS. *It has the inflorescence flower and habit of Thea, but the fruit is of a different kind.*

ESSENTIAL CHARACTER.

Cal. five-leaved. *Cor.* five-petalled. *Style* trifid, *Berry* juiceleſs, three-celled, many-ſeeded.

DESCRIPTIONS, *&c.*

1. The Lentil is an annual plant, and the leaſt of the pulſe kind which is cultivated. It riſes with weak ſtalks a foot and a half high, having pinnate leaves at each joint, compoſed of ſeveral pairs of narrow leaflets, terminated by a tendril, which ſupports it by faſtening about ſome other plant. The flowers come out on ſhort peduncles from the ſides of the branches; they are ſmall, of a pale purple colour, and three or four together. Legumes ſhort and flat, containing two or three flat, round ſeeds, a little convex in the middle. The flowers appear in may, and the ſeeds ripen in july.

[Scopoli thus deſcribes it in its wild ſtate.—Stems many, ſimple, angular, a foot high. The upper leaves only terminate in a tendril: leaflets alternate, lanceolate, emarginate protruding a ſhort dagger-point from the notch, the lower ſurface villoſe. Stipules entire, narrow. Peduncles villoſe, ſuſtaining from one to four flowers. Calyx villoſe. Standard of the corolla not emarginate. Sheath (or lower part of the filament) four-valved; the lateral valves have four ſtamens on each, the upper and lower one only. Germ pedunculed. Legume has from one to three ſeeds.—Spontaneous in the corn fields of France and Germany, the paſtures of Carniola, and the vineyards of the Valais.]

The common Lentil is cultivated either as fodder for cattle, or for the ſeeds which are uſed in ſoups. Theſe are commonly eaten by the poorer ſort in ſome iſlands of the Archipelago, and other warm countries. The contempt however in which they are held is apparent from the proverbial expreſſions, *Dives factus jam deſit gaudere lente*; and *mira de lente*.

[The cultivation of this pulſe does not ſeem to have been of very long ſtanding in England: for Gerarde ſays, 'theſe pulſes (great and little Lentils) do grow in my garden (1596); and it is reported unto me by thoſe of good credit, that at about Watford in Middleſex (Hertfordſhire) and other places of England, the huſbandmen do ſow them for their cattle, even as others do Tares.'—And Parkinſon (in 1640) only ſays, that 'they are ſown in ſome countries in our land, eſpecially the ſmaller ſort—but the greater doth very hardly come to maturity with us, if the ſeaſon be not kindly and dry.'

2. Root annual. Stems in open places ſlender, weak and much branched; but among corn ſupporting themſelves by tendrils to a foot or more in height: two edged and inclined to four-cornered. Stipules in pairs; the lower ſemiſagittate, the upper entire, or nearly ſo. Leaves pinnate; leaflets about five pairs (three to five *C.*), linear-lanceolate, approaching to linear; ſometimes lanceolate, and tapering to a point; moſtly inclined to alternate, terminated by a tendril, which is frequently ſimple. Flowers on ſlender capillary peduncles, as often ſingle as in pairs: calyx ſomewhat hairy: the lower ſegments longeſt. Standard of the corolla ſlightly emarginate, the border ſtreaked with purple; wings white and converging; keel obtuſe. Corolla (according to Linneus) violet, often blood-coloured. Legumes perfectly ſmooth, inclining to cylindric, and containing four ſeeds, nearly globular, brownish mottled with black. According to Scopoli there are ſometimes five ſeeds in a legume: and Mr. Woodward has remarked a variety near Cambridge, in which the legumes contain five, ſix or ſeven ſeeds, very rarely four. The ſtem was low and extremely branched. Theſe differences could not proceed from luxuriance of ſoil, as the ſpot where it grew was remarkably dry gravel.

This ſpecies is eaſily diſtinguiſhed from the next, for in that the pods are hairy and contain only two ſeeds; in this they are ſmooth and contain four; in that the flowers grow in a kind of cluſter, in this ſeldom more than two grow together. It is exceedingly fertile, one plant, caſually pulled up, having two hundred and twenty pods on it. It is found in moſt corn-fields, clinging to the corn, and if the ſeaſon favours its growth, ſometimes quite overcoming it.

3. Annual. Stems weak, much branched, climbing, quadrangular, ſtreaked, from one to two feet high. Lower ſtipules with two, three, or four awl-ſhaped teeth; the upper ones awl-ſhaped and entire. Leaflets moſtly linear, ſometimes lanceolate, eight to twelve pairs, ſomewhat alternate, terminated by a branched tendril. Peduncles axillary, ſhorter and not ſo ſlender as in the foregoing, bearing two, three or four flowers on very ſhort hairy pedicels; when two, ſeparate: if three, two together; if four, in pairs*. Calyx hairy, ſegments longer and more acute than in the foregoing. Legumes hairy, always containing two ſeeds.

* Three to five. Withering; three to eight. Curtis; four to ſix. Leers.

Eaſily diſtinguiſhed from the foregoing; the leaves not being pointed as in that, but truncate; the ſtipules divided into many more ſegments; the flowers, and conſequently the legumes growing in a kind of cluſter, being rough, and containing two ſeeds. It grows among corn, and is more deſtructive to it, being ſtronger and more prolific. In wet ſeaſons whole crops are overpowered by this plant. All ſorts of cattle eat it. Theſe two are called *Tine-Tare*, that with *ſmooth pods*, and this with *rough pods*.

They are common in the eaſtern countries, the preceding in Japan, and this in Cochinchina.

4. Larger than Lentil, climbing by means of bifid or trifid tendrils. Petioles horizontal. Leaflets ſixteen to eighteen, linear retuſe with a point. Stipules two, alternately larger, different in form: one very ſhort, lanceolate, the other oppoſite, five times larger, petioled pedate-multifid; the ſegments briſtle-form, very long, patulous. Peduncle one-flowered. Calyx three times ſhorter than the corolla, with the toothlets nearly equal. Standard compreſſed, whitiſh with violet veins. Legume large, ſomewhat nodding, containing two or three ſeeds, the ſize of Peas, compreſſed, with an obtuſe margin. It is annual; and according to Linnæus, the leaflets convolute.

Native of Ruſſia and the county of Nice. Near Herborn in Germany among Lentils. It flowers from may to july. Cultivated in 1731, by Mr. Miller.]

5. This is an annual plant, riſing with angular weak ſtalks a foot and half high, having at each joint one pinnate leaf, compoſed of fourteen or fifteen pairs of leaflets, very like thoſe of the Vetch, but narrower. The flowers come out from the ſides of the ſtalk, on peduncles an inch long, each ſuſtaining two pale-coloured flowers, which are ſucceeded by ſhort pods a little compreſſed, each containing three or four round ſeeds; the pods ſwell at the place where each ſeed is lodged. [Erect, not climbing. Stipules ovate, toothed. Leaflets eighteen to twenty-four, linear-oblong, retuſe with a point. Petiole drawn out at the end into a dagger-point, inſtead of a tendril. Peduncles two or three-flowered. Calyx only half the length of the corolla, with toothlets nearly equal, the two upper ones decuſſated. Standard ſlightly emarginate with a point. Germ linear, ſtraight, waved and plaited after flowering time. Legumes pendulous, jointed and knotted, containing three or four ſeeds, which are ſomewhat angular.

Native of France, Italy, and the Levant; alſo found in Germany and Switzerland, among Lentils. It flowers in june. Ray ſays it is common about Montpellier and Geneva.—Cultivated by Gerarde in 1597.]

The ſeeds ground to flour are ſometimes uſed in medicines abroad; and the green herb is employed for feeding cattle in ſome countries, but the plant is not worth cultivating for that purpoſe in England.

PROPAGATION AND CULTURE.

1. The ſeeds of Lentils are commonly ſown in march, where the land is dry, but in moiſt ground april is the beſt time. The uſual quantity of ſeed allowed to an acre is from a buſhel and half to two buſhels. If theſe are ſown in drills in the ſame manner as Peas, they will ſucceed better than when they are ſown broad-caſt: the drills ſhould be a foot and half aſunder, to allow room for the hoe to clean the ground between them; for if weeds be permitted to grow, they will overtop and ſtarve the Lentils. The ſeeds will ripen in july, when the plants ſhould be cut and dried, and the ſeeds afterwards threſhed out for uſe.

There is another ſort (or rather variety) which is cultivated by the name of French Lentil. It is the Lens major of Caſpar Bauhin, and is much better worth cultivating than the other. This pulſe is frequently called *Tills* in ſome parts of England.

2, 3. Theſe are ſmall annual Tares which grow wild among Wheat and Rie in many parts of England, and are not admitted into gardens. They may be eaſily deſtroyed in the fields if they are cut up when they begin to flower.

4, 5. May be cultivated in the ſame manner as common Lentils.

Root and ſtem-leaves alternate and three-parted, twice trifid; involucres awl-ſhaped, many-leaved ſomewhat ſpiny.

DESCRIPTIONS, *&c.*

[Theſe plants have ſomewhat the appearance of Thiſtles. The leaves are often ſpinous, as are alſo the involucres. The umbellets in ſome are incloſed in an involucre, which is often irregular and branched; in others they are diſperſed [a].

1. Root annual or biennial. Root-leaves bluntiſh, the ſerratures terminating in harmleſs ſpines. Stem a foot high or more, green, ſomewhat angular, dichotomous, ſpreading; with the extreme branches flexuoſe. The leaves on the branches oppoſite, ſtem-claſping, wedge-ſhaped, ſubconnate, with the edge toothed and ſemitrifid; the diviſions lanceolate, all the angles terminating in a purpliſh ſpine. The peduncle ſprings from the angles of the ſtem; it is ſtraight, ſhorter than the internode, triangular, ſtreaked on the ſides. The involucres are compoſed of ſix leaflets or thereabouts; they are horizontal and longer than the flower; the leaflets are lanceolate, nerved, and have a ſpine at the tip and at one or two of the ſerratures. Common receptacle cylindric, whence the flower is cylindric. Calyx of the florets five-toothed, the length of the corollet. Petals five, whitiſh, involute. Filaments double the length of the petals, white: anthers teſtaceous. Style two-parted, permanent. Seeds covered on all ſides with hemiſpheric dots. Chaffs linear, ſharp, the length of the florets. The whole plant is exceeding ſtinking [b]:—or rather has a very penetrating, ſtrong, though not very unſavoury ſmell [c].]

The lower leaves are ſix or ſeven inches long, narrow at the baſe, and enlarging upwards to an inch in breadth near the top, where they are rounded off on one ſide like a ſcymitar, they are finely ſerrate, and of a light green colour. The flowers are produced in ſmall ſeſſile heads, coming out at every diviſion of the ſtalks, and at the ends of the branches; they are of a dull white colour, and make little appearance. They appear in June and July, and the ſeeds ripen in autumn. [According to the Kew catalogue, this plant flowers from auguſt to october.

It is a native of the Weſt Indies, Mexico, Surinam and Virginia.—Cultivated here in 1714, by the Ducheſs of Beaufort [d].

All parts of the plant are reckoned very powerful antihyſterics, and much uſed by the negroes and poorer whites, on all occaſions of that nature; whence they call it *Fittweed*. It is chiefly adminiſtered in decoctions or infuſions [e].]

2. This has a perennial root, from which ariſe ſeveral long leaves, diſpoſed round the root, like thoſe of the Aloe or Yucca; they are of a gray colour, a foot long or more, and one inch and a half broad, ſtiff, and ending in ſpines. The ſtem is ſtrong, two feet high, and divides at top into ſeveral peduncles, each terminated by an oval head of flowers, which are white, with a little caſt of pale blue. They come out in july, but unleſs the ſeaſon is very warm, the ſeeds will not ripen in England.

[It has the appearance and leaves of a ſmall Bromelia, and is ciliate with capillary flexible ſoft ſpines. The chaffs of the flowers are larger. The involucres and chaffs quite entire [f].]

It grows naturally in Virginia and Carolina, where it is called Rattleſnake Weed, from its uſe in curing the bite of that venemous reptile.

[Introduced before 1699, by the Rev. John Baniſter; and cultivated in the botanic garden at Oxford [g].

3. Root perennial. Stem upright, round, furrowed or ſtreaked, whitiſh, about a foot and half in height, blueiſh at top, where it divides into three parts, each of which is terminated by a peduncled axillary flower. Lower leaves cordate-ovate, obtuſe, on long petioles, with unequal, mucronate notches about the edge, ſtem-leaves ſeſſile; the uppermoſt lobed, gaſhed, ſmaller, ſerrate, the notches ſpinuloſe. Flowers in terminating heads, fenced with a ſix-leaved involucre, ſpreading and reflex, the leaflets long-lanceolate, mucronate, as long as the flowers. Germ ſlightly angular. Calyx permanent, green with the edges and middle line ſilvery. Seeds flat on one ſide, convex on the other, hiſpid crowned with the calyx [h].]

It makes a pretty appearance when in flower, which is in july: eſpecially that with blue ſtalks and flowers, for there is a variety in which they are white, with the leaves of a lighter green. As this plant does not ſpread at the root, it ſhould be allowed a place in the pleaſure-ground.

[Cultivated in *1596* by Gerarde [i].

Native of Auſtria, Sileſia, Poland, Ruſſia.]

[a] Linn. ſyſt. [b] Sloane. [c] Hort. kew. [d] Browne. [e] Linn. ſpec. and ſyſt. [f] Mor. hiſt. [g] Krocker. [h] Hort. kew.

4. This puts out oblong plane leaves from the root, which are cut on their edges; the ſtalks riſe about a foot high, and branch out into many forked diviſions, which are regular, and have a ſmall head of flowers in each, ſitting very cloſe between the branches: theſe having no great beauty it is ſeldom cultivated except in botanic gardens.

[It flowers from june to auguſt.—Native of Spain and the Levant.

Cluſius firſt obſerved it in the garden of John Mouton, of Tournay, a learned apothecary, very ſkilful in botany; and thence named it *E. puſillum planum Moutoni.*—Cultivated in 1759 by Mr. Miller[x].

5. Root biennial, tuberous, approaching to the ſhape of the Radiſh. Leaves, when they firſt come out, ſmooth, round, undivided, but jagged about the edge, hanging on very long petioles, ſlender as hairs. Stem a foot high, with ſpiny heads at the top and in the axils, ſomewhat like thoſe of Pſyllium or Fleawort Plantain, with purple florets in them. Involucres of long, narrow, hard, prickly leaflets, much longer than in the common ſort[y].

Native of Spain, Sicily, and the Levant. Introduced in 1786, by Monſ. Vare[z].]

6. Root creeping, and running deep into the ground. Leaves roundiſh, ſtiff, gray, ſet with ſharp ſpines on the edges. Stems a foot high, branched, ſmooth, having at each joint leaves of the ſame form with the lower ones, but ſmaller.

[The root-leaves and lower ſtem-leaves are on broad claſping petioles, deeply divided into three lobes, which are plaited; the upper leaves are ſeſſile and ſtem-claſping[a].]

The flowers come out at the ends of the branches in roundiſh prickly heads, and are of a whitiſh blue colour; under each head is a range of narrow, ſtiff, prickly leaves, ſpreading like the rays of a ſtar. The flowers appear in july.

[By old Engliſh writers it is called Sea Holly, Sea Holme, and Sea Hulver.] It grows in great plenty on the ſandy and gravelly ſhores, in many parts of Britain and other countries of Europe.

[The young flowering-ſhoots eaten like Aſparagus are very grateful and nouriſhing[b].

The leaves are ſweetiſh, with a ſlight aromatic warmth and pungency. The roots are ſuppoſed to have the ſame aphrodiſiac virtues as the Orchis tribe. They are kept in the ſhops candied[c]; and are ſtill regarded by the Arabs as an excellent reſtorative.

Eryngo Roots were firſt candied in Colcheſter about the beginning of the 17th century, by Robert Buxton, apothecary. His apprentice, Samuel Great, continued this buſineſs, and it has ever ſince been carried on by the poſterity of the latter.

Morant's Colcheſter, p. 92.

7. Root perennial and ſtrong. The whole plant very ſtiff and pale green. Root-leaves and lower ſtem-leaves on long broad petioles, which embrace the ſtem, variouſly divided, doubly and trebly pinnatifid; the upper leaves ſeſſile, embracing the ſtem, which is long and trailing, bearing numerous heads of flowers[d]. Corolla blue, ſometimes white or yellowiſh[e]. Appearing in july and auguſt.

Native of moſt parts of Europe. In Britain not very common. On the coaſt near the ferry from Plymouth into Cornwall, near Newcaſtle upon Tyne; below Melling in Yorkſhire. Alſo far inland, oppoſite Brookhall, near Daventry, in Northamptonſhire. Gerarde cultivated it in his garden.]

8. The lower leaves are divided like the fingers of a hand, into five or ſix ſegments, which are very much cut at their extremities into many parts, and have ſmall ſpines. Stem about two feet high, with ſmaller and more divided leaves. The upper part of the ſtem, and alſo the heads of flowers, are of the fineſt amethyſtine colour, ſo that they make a very fine appearance.

[Leaves linear, ſemitrifid, at bottom ſubpinnate. Involucres lanceolate, longer than the head, fenced at the baſe with ſubulate briſtles interpoſed[f].

Native of the mountains of Styria.—Cultivated in England in 1664[g].] It flowers in july, and when the autumn proves dry, the ſeeds will ripen here.

[Scopoli cannot diſcover any other difference between this and the foregoing, except that the leaves are more gaſhed in the one than the other; he therefore looks upon them as one ſpecies.

β. The variety is ſmaller, and the involucre has trifid folioles[h].

9. Stem erect, rigid, a ſpan or a foot in height, very much branched, round, ſmooth, amethyſtine, as are alſo the branches and flowers. Branches alternate, divaricate, ſubdichotomous, three-ſided.—Root-leaves copious, an inch long, on flat petioles an inch and half in length, flexible, ſmooth; the lateral ſegments oblong, gaſhed at the tip, having ſpinuloſe teeth; the middle ſegment obovate, trifid; the lobes three-toothed, ſpinuloſe. Stem-leaves three-parted, half-ſtem-claſping: ſegments lanceolate, rigid, ſpiny, with a ſpiny tooth on each ſide at the baſe. Peduncles on the ſide and at the end of the branches, rigid, with a three-parted leaflet at the baſe of each. Head ſmall, few-flowered, ſometimes ſubſeſſile. Leaflets of the involucre longer by half than the head, lanceolate, concave, rigid, entire, ending at top in a pungent ſpine, without any briſtles at the baſe of the involucre, as in *E. amethyſtinum*. Chaffs awl-ſhaped, rigid, pungent, the length of the florets.

Gathered in the dry plains of the kingdom of Tunis, by Vahl[i].

10. Root perennial. The leaves are cordate and toothed, the lower on long petioles, the upper ſtem-claſping. The lower leaves reſemble thoſe of *Cacalia*, but are more acute, and the teeth end in a ſoft ſpine. Amethyſtine leaves ſurround the oblong head of flowers; ſome of them briſtle-form and reflex, other pinnatifid and lanceolate. Corolla white. Anthers green[k].

It is a plant, ſays Villars, curious to ſee, on account of the beauty of the involucres, which are of a vinous azure blue, mixed with green and white, ſcarcely prickly; the heads of flowers are much elongated, cylindric in the lower, and ſuddenly rounded in the upper part. This ſort has been confounded with the next by the Bauhins, and Linneus, but it has the lower leaves entire as in *E. planum*, whereas in the enſuing ſpecies they are cut to the centre. The leaves of this are ſimple, ſerrate and ſmooth; thoſe on the ſtem trifid, and the upper or floral leaves, coloured, palmate and fringed.

Native of the mountains of Switzerland, Dauphiné and Italy.——Cultivated in 1752, by Mr. Miller[l].

11. Height from eight inches to a foot. Stems thick, white, ſtrong, and branched from the bottom. The lower leaves are at firſt entire, and afterwards winged, toothed or a little ſpiny, then palmate-laciniate, ſinuated, ſpiny or cut on the ſides; at the baſe of each branch is a ſmaller leaf. Peduncles ſtrong, ſolid, each ſupporting a ſingle conical head, leſs lengthened out than in the preceding ſort, but more rough like that of the Teaſel. Involucre frequently compoſed of a double row of ſeveral rough, prickly, ſilvery leaves, ſimple or divided into three parts, longer than the flowers. This plant is lower, rougher, thicker and more branched than the preceding; the leaves continue ſome years, awaiting the growth of the root neceſſary to produce the ſtem: and when the fructification is completed the whole periſhes[m]. The chaffs are awl-ſhaped, rigid, and longer than the flower[n].

Gouan, who firſt clearly diſtinguiſhed it, ſays that it approaches very near to *E. tricuſpidatum*, but differs from it in having the leaves digitate and biternate, but not palmate; the chaffs quite entire, not three-cuſped.

Mr. Miller, who cultivated this ſpecies in 1731[o], ſays that] the ſtalks riſe about two feet high, that the

flowers are of a light blue colour, in very large heads, that it flowers in june and july, and that the ſeeds ripen here in autumn.

[Native of the South of France.]

PROPAGATION AND CULTURE.

1. As this plant is a native of hot countries, it will not thrive in England, but in a warm ſtove. It is propagated by ſeeds, which muſt be ſown on a hot-bed; and when the plants are fit to remove, they ſhould be each planted in a ſmall pot, and plunged into the bark-bed, and afterwards treated like other tender plants from the ſame country; the ſecond year they will produce flowers and ſeeds, ſoon after which they commonly decay.

2. This ſort is propagated by ſeeds, which, if ſown in pots and plunged into a moderate hot-bed, will come up much ſooner than thoſe which are ſown in the full ground, whereby they will be much ſtronger before the winter. When the plants are fit to remove, they ſhould be each planted in a ſeparate ſmall pot, filled with light earth; and if they are plunged into a moderate hot-bed, it will forward their taking root; then they muſt be gradually inured to bear the open air, into which they may be removed toward the latter end of may, and placed among other hardy exotic plants. When the plants have filled theſe pots with their roots, ſome of them may be ſhaken out, and planted in a warm border; the others may be put into larger pots, and in the autumn placed under a common frame, where they may be expoſed to the free air in mild weather, but ſheltered from ſevere froſt: the following ſpring theſe may be turned out of the pots, and planted in a warm ſituation, where they will endure the cold of our ordinary winters very well; and if in ſevere froſt they are covered with Straw, Pea-haulm, or any ſuch light covering, it will ſecure them from injury.

3. This is propagated by ſeeds, which if ſown in the autumn, will more certainly ſucceed than when ſown in the ſpring, for the latter commonly remain in the ground a year before they vegetate; and if the ſeeds are ſown where the plants are to remain, they will flower ſtronger than thoſe which are tranſplanted; for as they have long downright roots, ſo theſe are commonly broken in taking out of the ground, which greatly weakens the plants. The culture they require is to thin them where they are too near, keep them clean from weeds, and dig the ground about them every ſpring before they ſhoot.

4. Having no great beauty, it is ſeldom cultivated in gardens.

6. This ſort will grow in a garden, if the roots are planted in a gravelly ſoil, and produce flowers annually; but the roots will not grow near ſo large or fleſhy as thoſe which grow on the ſea-ſhore, where they are overflowed with ſalt water. The beſt time to tranſplant the roots is in autumn, when the leaves decay; the young roots are much better to move than the old, becauſe being furniſhed with fibres, they will readily take root: when theſe are fixed in the ground, they ſhould remain unremoved; and if they are kept clean from weeds, it is all the culture they will require.

7. The ſeventh ſort is a very troubleſome weed, for the roots run deep into the ground, and are not eaſily deſtroyed by the plough; they ſpread and multiply greatly in the ground, to the prejudice of whatever is ſown or planted on the land, therefore this plant is not admitted into gardens.

The eighth, tenth, and eleventh ſorts are propagated by ſeeds in the ſame manner as the third, and require the ſame treatment.

DESCRIPTIONS, *&c.*

1. Root annual. Stem from one to two feet high, upright, round, finely grooved, beſet with numerous ſhort, rough hairs, branched, and for the moſt part purpliſh, particularly at the angles of the branches, which ſpread very much. Leaves alternate, petioled, ſlightly downy on both ſides, ſcabrous underneath, particularly on the midrib and nerves, pinnatifid, the ſegments oppoſite, oblong, ſerrate-toothed, the end one largeſt and connected with the next to it. Racemes of flowers terminating, roundiſh; of fruits filiform, elongated, naked, patebeſcent. Leaflets of the calyx of a pale colour, linear-oval, bluntiſh, concave, pubeſcent. Petals of a dull yellow, wedge-ſhaped, veined. Anthers cordate, ſharp, bent ſomewhat upward. Style pubeſcent. Stigma round, flatriſh, emarginate, almoſt the height of the ſtamens. Siliqua cylindric, finely grooved, green or purple, pubeſcent, preſſed to the ſtalk; not opening ſpontaneouſly whilſt on the plant. Seeds dingy yellow, obliquely truncate at both ends, immerſed in the partition, and eight in each cell. Viewed as it comes into bloſſom, and when its flowering branches ſhoot out horizontally to a great length, it ſcarcely ſeems to be the ſame plant. It is common on dry banks, under walls, pales, and in waſte places: from may or june to ſeptember[a]. Beſides its name of *Hedge-Muſtard*, it has alſo thoſe of *Bank Creſſes* and *Scrambling Rocket*. Turner calls it *Winter Creſſes*.

In Getman it is named *der Hederich, Wegeſenf, wilder Senf, falcher Waſſerſenf, das gelbe Eiſenkraut, das Weibchen des Eiſenkrauts, Kreuzkraut*. In Daniſh *Vild Senep, Veyſenep*. In Swediſh *Väggkraſſa*. In French *le Velar, la Tortelle, l'herbe au Chantre*. In Italian *Eriſamo*. In Spaniſh *Jaramago, hierba de San Alberto, Irion*. In Portugueze *Eriſimo*. In Ruſſian *Gorczycza polna* and *Pſzonak ziele*.

It is warm and acrid to the taſte, and when cultivated, is uſed as a ſpring potherb. Birds are fond of the ſeeds. Sheep and goats eat it. Cows, horſes and ſwine refuſe it.

Rondeletius cured a hoarſeneſs occaſioned by loud ſpeaking, with this herb, in a few days[b]. The juice of it is beyond any thing in diſeaſes of the throat[c].

This and ſome others of the claſs, are apt to come up among the aſhes, where charcoal has been made, or where there has been any conſiderable fire[d].

2. Root perennial. Stem a foot or eighteen inches high, ſmooth, round, deeply furrowed, much branched. Leaves ſmooth, dark green, having two or three pairs of roundiſh lobes, connected to a broad foliaceous rib; the extreme lobe much the largeſt, and either of an oval or blunt rhomboidal figure, ſlightly indented on the edges: but they vary much in form. Flowers in racemes or thick ſpikes at the ends of the ſtem and branches; peduncles compreſſed quadrangular. Calyx green, caducous; two of the leaflets larger, with a helmet-ſhaped hollow at the top. Petals yellow, much longer than the calyx. Nectary conſiſts of four glands, two between the longer ſtamens, and two ſupporting the ſhorter ones. Siliques upright, parallel to the ſpike-ſtalk, with four obſcure angles. Seeds roughiſh, finely dotted and reticulated, twenty in number, in each cell ten[e].

Banks of ditches and ſtreams, in watery places; ſometimes in cultivated fields and even on walls. It flowers from may to july. It is called *Winter Rocket* as well as *Winter Creſs*: and *herb S. barbaræ*. In German it is named *die Winterkreſſe, Barbenkraut, Barbelkraut, Rapunzel, Senfkraut, Schwädeſens, Hlabichtskraut, gelber Beyfuſs, falſche Ruman*. In Daniſh *Vinterkars*. In Swediſh *Vinterkraſſe*. In French *la Barbaree, l'herbe Sainte Barbe, l'herbe aux charpentiers, la Julienne jaune, Requette*. In Italian *Barbarea, erba di Santa Barbara, Ruchetta*. In Spaniſh *Hierba de Santa Barbara, Ruqueta*. In Portugueze *Herva de S. Barbara*.

The common people in Sweden uſe the leaves in ſalads early in the ſpring, and late in the autumn: they alſo boil them as Cale. Some alſo in England cultivate it for ſpring ſalad, under the name of *French* or *American Creſs*; but it has to moſt people a bitter, unpleaſant taſte[f].

Varieties.

There are ſeveral varieties of Winter Creſs. One is made a diſtinct ſpecies by Miller, under the name of *Eryſimum vernum*. E. præcox. *Smith. brit.* 707. This is variety β. of Linneus's ſpecies plantarum and *Siſymbrium Eruceæ folio glabro, minus & præcocius*, Tournef. inſt. 226.—It is diſtinguiſhed by Ray (hiſt. 809.) as having ſmaller leaves, more frequently ſinuated, the pods thicker, and the ſeeds larger, paler brown inclining to white.—Petiver has figured it (t. 46. f. 2.) under the name of *Early Winter Creſs*; and ſays that it flowers in april.

A variety with double flowers (Barbarea flore pleno, *Park.*) is common in the gardens, under the name of *Yellow Rocket*[g].

Villars inſiſts that Siſymbrium Barbarea of Linneus, Eryſimum orientale of Miller, n. 4. is nothing more than a variety of this.

3. Root biennial. Stem upright, from two to three

[f] Linn. ſuec. Withering, Stokes in Withering, Lightfoot.

[g] Wood. Mſs.

three feet high, round, ſmooth, ſomewhat ſtriated, at bottom purple and ſlightly hairy, at top branched. The branches are few, alternate and upright. Leaves alternate, petioled, veiny and ſomewhat wrinkled; the lower ones on longer petioles, bluntly notched or ſcooped and rounded at the end; the upper ones ſharp, and even acuminate, unequally toothed: there are a few hairs at the baſe of the foot-ſtalk. Flowers in a corymb; terminating, upright, on peduncles the length of the flowers. Leaflets of the calyx pale green, obtuſe, deciduous, hollow at the tip. Corolla white, petals obovate, border ſpreading, marked with a few veins. Nectary of four glands, two between the longer ſtamens, and two ſupporting the ſhorter ſtamens. Silique two inches long, obſcurely quadrangular, with a fine prominent line between the angles. Seeds brown, ſhining, ſtriated, truncate at both ends, partly buried in the partition [b].

Common by hedge ſides, on banks and in ſhady places; flowering in april and may.—From its place of growth it has the vulgar name of *Jack by the hedge*. And having a ſtrong ſmell and taſte of Garlic, it is uſed by the country people in ſauces, with bread and butter, ſalted meat, and with lettuce in ſalads: hence it has another vulgar name of *Sauce alone*. In German it is call *das Knoblauchkraut, der Knoblauchhederich, Lauchel, Waldknoblauch, Ramſen, Rampen, Ramſchelwurzel, Gerinſel, Salſekraut, Saſtkraut*. In Danish *Hvid løgſurt, Gaſtekaal*. In Swediſh *Hvitlökſört*. In French *L'Alliaire, l'herbe des aux, l'herbe aux aillets*. In Italian, Spaniſh and Portugueze *Alliaria*.

According to Linneus's obſervation, horſes, ſheep and ſwine refuſe it, but kine and goats eat it. If eaten by cows, it gives a ſtrong diſagreeable taſte to the milk. When it grows in poultry yards the fowls eat it, and it gives an intolerable rank taſte to their fleſh [l]. The ſeeds excite ſneezing [k].

The leaves are recommended internally, as ſudorifics and deobſtruents, of the nature of Garlic, but much milder; externally, as antiſeptics, in gangrenes and cancerous ulcers [l].

4. Stature of *Siſymbrium polyceratium*, but the racemes are oppoſite to the leaves, long, and axiliary; the ſiliques are long, filiform and angular.—Stem upright, angular. Leaves lanceolate, ſharply toothed. Flowers ſmall, pale. Stigmas very ſlightly emarginate, not two lobed [n].

Annual. Native of Spain, Bohemia, Sileſia, Auſtria, Italy. It flowers in may and june. Introduced in 1772, by Monſ. Richard [b].

5. This has very much the air or habit of *Cheiranthus Eryſimoides*, except that the flowers are ſmaller and the ſiliques patulous. The ſtigma in this is ſmall and hardly divided, in the next ſpecies it is formed as it were of two divaricated knobs [o].

Root annual. Stem from one to two cubits in height, upright, ſtiff, ſtreaked, rough, uſually ſimple, ſometimes branched a little; (others ſay, very much branched.) Leaves roughiſh, the midrib running down the ſtem, the uppermoſt ſometimes a little toothed. Corolla ſmall, yellow [p]. Silique an inch long, rhomb-quadrangular, obſcurely knobbed where the ſeeds lie: partition membranaceous, contrary to the valves, or certainly narrower than the ſilique: valves keeled on the outſide at an acute angle. Receptacle between the valves, filiform, ending in the very ſhort ſtyle with a blunt ſtigma. Seeds about eighteen in each cell, ovate, a little turgid, beaked, of a yellowiſh brown colour [q]. They are a moſtly bitter, as Wormſeed or Coloquintida [r].

In moſt parts of Europe. In England not common. In the oiſter-boits near Ely, and on the bank of the river between the bridge and the city. In the corn fields about Elden, and among turneps near Bungay in Suffolk. Ainburne in Derbyſhire.—It flowers from may to auguſt.

All cattle eat it. The country people give the ſeeds to deſtroy worms, with good effect; hence its name of *Treacle Wormſeed*.

6. It differs from the foregoing ſpecies, not only in having ſerrate leaves, but longer ſiliques not ſtanding ſo wide from the ſtem, and larger flowers. It differs from *Cheiranthus eryſimoides*, in having flowers of only half the ſize, the top of the ſtyle or the ſtigma emarginate indeed, but not two-lobed, and the ſiliques by no means tomentoſe, although the piſtils or germs be hairy [s].

According to Villars it is much ſmaller than the preceding ſpecies, the ſtem not being more than eight inches high, ſimple or unbranched. The lower leaves are toothed, and reſemble thoſe of *Crepis virens*, being whitiſh or aſh-coloured: the ſtem-leaves become linear. The flowers terminate the plant, and the petals are of a pale yellow. The ſiliques are hard, a little villoſe, and approximate to the ſtem.

He adds that it is difficult to diſtinguiſh this plant from *Cheiranthus eryſimoides*, except by its cut leaves and the ſmallneſs of the flowers; and that he therefore conſiders them as varieties of the ſame ſpecies, though Linneus has inſerted them in diſferent genera.

See Cheiranthus eryſimoides.

According to Retzius, the root is biennial. Stems upright, ſtiff, ſometimes branched, many-angled, ſmooth. Leaves alternate, ſmooth, very remotely toothed, by no means ſerrate. Flowers in racemes, yellow, ſmelling faintly. Calyx greeniſh yellow, brown at the end. Petals almoſt linear, truncate. A ſmall gland at the ſhorter ſtamens. Siliques upright, ſtiff, regularly quadrangular, ending in an emarginate ſtigma. The plant under the ſame name in Pollich is a different ſpecies.

Native of Sweden, Denmark, France, Germany, Auſtria, Italy.

7. Linneus has not this plant, and ſeems to have confounded it with *Braſſica campeſtris*, from which it differs, in having a more diffuſed habit, a white flower, a longer ſilique entirely quadrangular; whereas that has the ſilique cylindric, looſe, dry, wrinkled and veined, ending in a ſoft ſubular horn. Annual.

Native of Germany and the Levant [t].

See Braſſica orientalis.

8. Annual. Flowers ſmall, yellow. Calyx yellowiſh, hairy on the outſide. Style permanent, capillary, the length of the horns. Stigma entire. Siliques approximating, preſſed cloſe, from anceps four-cornered, hairy, three or four lines long, with two horns at the end.

Native of the Canary iſlands. Found by Mr. Francis Maſſon, and introduced in 1779.—It flowers in auguſt and ſeptember [u].]

PROPAGATION AND CULTURE.

In general theſe plants are only admitted into botanic gardens. The three firſt are common weeds, and will ſcatter their ſeeds wherever they are admitted ſo as ſoon to become troubleſome. Moſt of them perith after they have ripened their ſeeds, but the fifth ſort will abide ſeveral years in a dry lean ſoil, or on a wall: in rich land it ſoon decays. They may be all propagated by ſowing their ſeeds in the autumn, where they are to remain; and they require no culture but to thin them, and keep them clean from weeds.

[The laſt ſpecies requires the protection of a green-houſe; all the others are hardy enough, and the ſecond, as has already been mentioned, is cultivated by ſome in the kitchen garden, as a warm ſpring ſalad herb, under the name of French or American Creſs. If permitted to ſcatter its ſeeds, it will come up of itſelf in ſufficient quantity.

ERYSIMUM. See *Braſſica, Cheiranthus, Sinapis*, and *Siſymbrium*.

Leaves ternate unarmed lanceolate, banner of the corolla convolute.

DESCRIPTIONS, *&c.*

These are small trees prickly or unarmed, or else shrubs sometimes almost herbaceous; leaves as in *Dolichos*, ternate, stipulaceous, the petiolules jointed and awned or glandular, very seldom simple; flowers in fascicles from the axils or in spikes at the ends of the stem and branches, often scarlet[a].]

1. This has a large woody root, from which fresh shoots come out every spring, growing to the height of about two feet. [They seldom throw out branches, and are sometimes perennial. The petioles are usually prickly underneath: there is commonly a prickle also under the common petiole on the stem, and sometimes but seldom a prickle or two scattered about the stem[b].] Leaflets hastate deep green. The upper part of the stalks are terminated by a long bunch or spike of scarlet flowers. [The bunches are erect; the pedicels in threes, each sustaining one flower. Calyx undivided, without the melliferous gland at the base. Banner of the corolla deep red. Wings and keel very short. The tenth stamen distinct[c].] Legumes five or six inches long, containing five or six scarlet seeds. This species flowers in september, but never produces seeds in England. It grows naturally in South Carolina, whence Mr. Catesby sent the seeds in the year 1724, and many plants were then raised, in several curious gardens. [It was also sent afterwards to Jussieu from the banks of the Mississipi[d].]

2. The seeds of this are not half so large as those of the next sort, and are of a bright scarlet colour; the leaves are also much smaller, and have long acute points; the branches are very closely armed with crooked greenish spines, as are also the ribs and foot-stalks of the leaves. The flowers grow in very long close spikes, and are of a beautiful scarlet colour.

[Cultivated in 1759, by Mr. Miller[e],] who says that he received the seeds from La Vera Cruz, and afterwards from the Cape of Good Hope.

3. This has a thick woody stem, which rises about ten or twelve feet high in this country, but where it is a native it grows to twice that height, sending out many strong irregular branches, which are covered with a brown bark. Leaves on long foot-stalks; the middle leaflet much larger than the other two; they are all heart-shaped, smooth, and of a deep green colour. The flowers come out at the ends of the branches, in short thick close spikes; they are of a deep scarlet colour, and make a fine appearance; they are commonly in beauty in may and june, but are not succeeded by pods here: in America they have thick swelling crooked pods, containing large seeds of a reddish purple colour. The leaves fall off in spring, and in autumn new leaves put forth, which continue green all the winter. The flowers do not appear till the leaves drop.

[Dr. Browne thinks it is not a native of Jamaica, but that it was introduced by the Spaniards, who planted it among their Cacao trees, where the walks were most exposed to the weather, in order to break the force of the winds, whence it acquired the appellation of *Mader de Cocoa*, among them.—In Jamaica it is called the *Coral* or *Red Bean-tree*. Cultivated in 1714, by the Duchess of Beaufort[f].

There is some difference between the western and eastern plant; the prickles in the latter are blackish: but the difference seems scarcely sufficient to make them distinct species. The leaves sleep about noon by *conniving* or clapping together[g].

This is a native of the Society isles, and of the southern part of China and Cochinchina.]

4. This has shrubby branched stalks, seldom above eight or nine feet high, armed in every part with strong crooked black spines. The leaves are smaller than those of the preceding, and have a nearer resemblance to the first; the foot-stalks are armed with the same sort of spines, and the midrib has also some which are smaller and not so black; the flowers are of a paler scarlet, and grow in looser spikes. The seeds are as large as those of the third sort, but of a dark purple colour.

[Linnæus describes his plant, when only a year old, as very like *E. Corallodendron*, from which however

[a] Jussieu. [b] Linn. [c] Ibid. [d] Hort. cliff. [e] Hort. kew. [f] Ibid. [g] Linn.

ever it differed in the leaflets having a white rachis and ribs with very ſmall prickles on both ſurfaces, whereas the leaflets of that are green and unarmed. That has two glands at the baſe of the terminating leaflet; this has none; but the ſtem and petioles are prickly in both.]

This tree is generally planted in the Eaſt Indies for a ſupport to the Pepper plants. [Cultivated in 1768, by Mr. Miller.

5. This is a very lofty tree without and prickles on the trunk. The branches are ſtiff. The leaflets ovate-oblong and quite entire. The petioles elongated, having frequently one or two recurved prickles underneath; on this petiole at the baſe of the pedicels on each ſide is a gland, and there are alſo two glands on the middle of the intermediate pedicel. Flowers two or three, axillary, purple, on ſeparate peduncles, reſupinate. Calyx bell-ſhaped, two-lipped, the lower lip dagger-pointed. Banner ovate-cordate, reflex, emarginate: wings ſhorter than the calyx: keel ſubfalcate, ſharp, compreſſed, almoſt the length of the banner. Stamens diadelphous, the nine lower ones almoſt wholly united, the length of the keel: anthers oblong. Germ oblong, villoſe: ſtyle ſubulate: ſtigma with a minute dot[h].—Native of Braſil. Introduced in 1771, by Francis Bearſly, Eſq.[i]

6. Native of South America.

7. Stem arboreous, eight feet high, with a brown bark like that of Hemp, and many ſhort ſcattered prickles. The branches are diffuſed. Leaves ſcattered, petioled: leaflets quite entire, ſmooth. Flowers of a brown-red colour, in a terminating raceme. Calyx ſub-bilabiate, the lips entire and erect, having a melliferous pore above the baſe. Standard of the corolla very long, blunt, ſubturbinate, rolled into a tube, bent back at the baſe. Legumes columnar, jointed, hairy. Seeds oblong.

Native of Cochinchina, on the banks of rivers[k].

Mr. Bruce affirms, that the ſeeds of one ſpecies of Erythrina are called *Carats*, and are uſed in weighing gold and precious ſtones[l].]

Mr. Miller mentions ſeveral other ſorts or varieties of this fine genus. As one which he names *Erythrina inermis, n. 6.* The pods of which are longer, and not more than half ſo thick as thoſe of the third ſort; the ſeeds of a bright ſcarlet, longer and more ſlender than thoſe of the others; the leaves ſmall and acute-pointed; the ſtalks ſmooth and without ſpines. It does not grow very large, but ſhoots out into branches at a little diſtance from the ground, and theſe grow erect, ſo as to form a buſhy ſhrub. The flowers come out at the ends of the branches in ſhort ſpikes. The wings of the corolla are longer than in the other ſorts, and the whole flower is more cloſed. It is a native of the iſlands in the Weſt Indies.

A ſecond which he raiſed from ſmall ſeeds of a bright ſcarlet colour, that were ſent him from the Cape of Good Hope. The plants had no ſpines, the leaves were much larger than the other ſorts, their ſtems were ſtrong, and they had the appearance of growing to large trees.

He raiſed a variety of the ſecond ſort, with paler flowers and ſeeds, and the plants leſs thorny.

Alſo a variety of the third ſort, which he received from the iſland of Barbuda, with the flowers and pods very ſhort, the ſtamens much longer than the petals, the pods very ſhort and crooked, but rather thicker than thoſe of the third ſort, the leaves, ſtems and branches armed with ſpines.

PROPAGATION AND CULTURE.

Theſe plants are beſt propagated by ſeeds procured from the countries where they grow naturally, for they do not produce any here. Sow them in ſmall pots, and plunge them into a moderate hot-bed; where, if the ſeeds be good, the plants will come up in a month or five weeks. When they are two inches high, ſhake them carefully out of the pots, and plant each in a ſeparate ſmall pot, filled with light earth, and plunged into a moderate hot-bed of tanners bark, ſhading them from the ſun till they have taken new root, admitting a large ſhare of air to them when the weather is warm, to prevent their being drawn up weak, and giving them more air as the plants increaſe in ſtrength: water them frequently but moderately; for too much moiſture will rot the fibres of their roots. In the autumn remove the plants into the ſtove; and for the two or three firſt winters they will require more heat than when they have acquired greater ſtrength. Water them two or three times a week whilſt the leaves are in vigour; but when theſe are fallen, moiſture is very hurtful to them.

They may alſo be increaſed by cuttings, planted in pots during the ſummer months, and plunged into a hot-bed; but ſeedling plants are beſt.

The firſt ſort may be kept through the winter in a warm green-houſe, but in this ſituation is rarely flowers.

The ſecond is frequently planted in the gardens near Liſbon, where it annually flowers, and the ſeeds ripen: but in England this and the other ſorts ſeldom flower, with any treatment we can give them.

DESCRIPTION, *&c.*

Mr. Miller makes two diſtinct ſpecies. The firſt with two ovate leaves joined at their baſe, three inches long and one inch and a half broad in the middle, gradually leſſening towards the ends; theſe at firſt embrace each other, incloſing the flower, but afterward

[h] Linn. mant. [i] Hort. kew. [k] Loureiro. [l] Travels, vol. 5, art. Koara.

afterwards they ſpread flat upon the ground; they are ſpotted with purple and white all over their ſurface. Between them riſes a ſingle, ſmooth, purple, naked ſtalk, about four inches high, ſuſtaining one flower, which hangs down; the petals are reflex and ſpread open to their baſe; their colour is commonly purple, but ſometimes white. Stamens purple, ſtanding cloſe about the ſtyle, which is longer than them. The roots are white, oblong, and fleſhy, ſhaped like a tooth; whence this plant has the name of Dog's-tooth in Engliſh. [The ſame idea has governed the name in all the European languages. In German it is *Hundszahn*. In Swediſh and Daniſh *Hundetand*. In French *Le dent de chien*. In Italian *Dente di cane*. In Spaniſh *Diente de perro*. In Portugueze *Dente de Cão*. In Ruſſian *Kandik*.]

β. The ſecond differs in the ſhape of its leaves, which are longer and narrower; and the flowers are a little larger but not ſo well coloured.

γ. The leaves are of a darker green, and the flower is of a pale yellow colour [a].

Theſe grow naturally in the South of France, Italy, Savoy, Switzerland, Auſtria, Friuli, Siberia. The laſt in Virginia.—Ray obſerved the firſt with a purple flower near Turin, in his way to Aſti, in april; and with a white flower between Novi and Genoa. Cluſius found this variety near Gratz in Stiria; and John Bauhin at la Bâtie near Geneva, flowering in march, where I alſo gathered it on the 15th of march 1779.

Cultivated by Gerarde in 1596.]

PROPAGATION AND CULTURE.

This in increaſed by offſets from the roots, which they do not ſend out very plentifully. It is not therefore ſo common in gardens as moſt other flowers of the ſpring ſeaſon. It loves a ſhady ſituation and a light loamy ſoil. It may be tranſplanted any time after the beginning of june, when the leaves will be quite decayed, till the middle of ſeptember; but the roots ſhould not be too often removed, nor ſhould they be kept very long out of the ground, for if they ſhrink they will frequently rot. They ſhould not be planted ſcattering in the borders of the flower-garden, but in patches; and thus diſpoſed, they will make a good appearance.

DESCRIPTIONS, &c.

1. Stem ſhrubby, even, with long ſpreading and ſomewhat rugged branches. Leaves petioled, alternate, obovate, narrower at the baſe, entire, veined, ſubglaucous underneath, deciduous. Flowers in alternate bundles, on ſhort peduncles, ſmall and white. Petals with claws, inſerted into the edge of the ſegments of the calyx, oblong, convex, entire. Nectareous ſcales in the throat of the corolla, ſurrounding the ſtamens, waved about the edge. Filaments during the time of flowering connate above the middle, afterwards cut more deeply, awl-ſhaped and white. Anthers ovate, minute, yellow. Germ roundiſh. Styles awl-ſhaped, ſpreading very much. Stigmas capitate-peltate. Fruit an oblong drupe, reſembling that of the Barberry, acuminate, ſcarlet, including an oblong attenuated hard nucleus or nut [b].

According to Jacquin, it is a tree twelve feet in height, with numerous branches, frequently coming out from the very bottom of the trunk, with the bark of a dark brown colour, and the wood ſolid and pale brown, but never reddiſh, as Brown repreſents it to be. Flowers very ſweet, having the odour of the Jonquil but milder. The fruit does not ſeem to be eaten by any animal.

Browne ſays it is a ſmall but beautiful tree: the leaves of an oval form, and marked with two ſlender longitudinal lines upon the back, which were the utmoſt limits of that part of the leaf which was expoſed, while it lay in a folded ſtate. The flowers grow in little cluſters, and are very thick upon the branches. The inward bark is of a fleſh colour, and the wood of a reddiſh brown. It is reckoned an excellent timber-wood, for the ſize of the tree, which ſeldom exceeds ſixteen or eighteen feet in height, and five or ſix inches in diameter. Natives of the Weſt Indies in dry coppices.

Dr. Browne has another ſpecies, which he calls, *ſmall round leafed Erythroxylon or Redwood, with very ſlender branches.* This tree, he ſays, differs much from the foregoing, both in ſhape and manner of growth. It grows in the low lands of Jamaica, like the other, and riſes commonly to the height of eighteen or twenty feet. Its leaves are roundiſh and ſmall; and the branches very ſlender. *Browne n.* 2. *p.* 278.

2. This is a ſhrub three feet in height, having altogether the habit of the preceding, but the leaves ovate, obtuſe, quite entire, without any lines underneath. Fruit orange-coloured. It can hardly be a variety of the *areolatum*.

Native of the Havanna on rocks near the coaſt [c].

3. The branches are covered with a browniſh wrinkled dotted bark, compreſſed at top, and toothletted from the fallen leaves. Scales on the branchlets awl-ſhaped and deciduous. Leaves petioled, glaucous underneath. Peduncles capillary, nearly the ſame length with the leaves.

4. Branches ſmooth, covered with an aſh-coloured bark, round below, but compreſſed at top, among the leaves at top having ovate, half-embracing, ſhort, acute, keeled ſcales, with a longitudinal groove on the back, at the baſe of which is inſerted an awn the length of the ſcale. Branchlets axillary, alternate, compreſſed, the lower ones leafy, the upper leafleſs, toothed with ovate, imbricate, copious ſcales, ſpreading a little at the tip. The ends of the branches are of the ſame ſtructure. Leaves on very ſhort pe-

[b] Swartz. [c] Jacquin.

tioles,

tioles, alternate, two inches and more in length, ſometimes narrower towards the lower part, ending in a blunt point, acute at the baſe, very ſmooth, very finely veined, without any longitudinal nerves, paler underneath, quite entire. Peduncles on the branchlets, from the axils of the ſcales, ſolitary or in pairs, alternate, hardly an inch in length, angular, a little thicker towards the top, ſpreading. Segments of the calyx ovate, acute.

Native of the Weſt Indies: obſerved in Cayenne by Rohr.

5. Branches round at bottom, compreſſed at top, ſmooth, covered with a grey bark, at bottom, among the leaves having approximating ſcales, of an ovate-lanceolate form, half-embracing, keeled, ſtriated, purpliſh, acute; near the baſe on the outſide is a brown awl-ſhaped awn, the length of the ſcale, concealed within the dorſal groove of the ſcales. There are two other bracte-ſhaped ſcales, one on each ſide, a little above the petiole: they are lanceolate, attenuated, and the ſame length with the flower. Leaves petioled, alternate, a ſpan in length, ſharp at both ends, ſmooth, glaucous and veined with purple underneath, quite entire. Petioles very ſhort, browniſh. Peduncles from the axils of the ſcales and leaves, ſeveral, one-flowered, with ſeveral linear-lanceolate keeled ſcales interpoſed, a little ſhorter than the peduncles, the inmoſt narrower and ſhorter. The flowers, before they are unfolded, ovate, mucronate, with five prominent angles. Calyx coloured, with ovate acuminate ſegments. Petals linear, obtuſe.

Obſerved in Cayenne by Rohr[t].

Leaves ſerrulate ending in a ſmall dagger-point veiny underneath.

2. Eſcallonia ſerrata.

Smith ic. ined. 2. 31.

Leaves ſerrate ſubretuſe veinleſs underneath.

DESCRIPTIONS, &c.

1. This is a branching, leafy ſhrub. Branches wandlike, obſcurely angular, covered with a ſmooth, chinky, deciduous bark. Branchlets alternate, ſpreading, angular, cloſely leaved, one-flowered. Leaves alternate, ſpreading, obovate, obtuſe with a little dagger-point, minutely ſerrulate eſpecially towards the tip, of an even ſurface on both ſides, almoſt veinleſs above, underneath paler and veined, attenuated at the baſe into a ſhort, channelled, decurrent petiole, more or leſs glandular-ciliate at the edge. Flowers terminating, ſolitary, peduncled, upright. No proper bractes, but ſmall leaves like the others, only more plainly ſerrate, approaching the flower. Peduncles ſtraitiſh, angular, glandulous. Diviſions of the calyx from erect ſpreading, acuminate, bowed back at the tip, ſomewhat pubeſcent about the edge. Petals upright, bowed back at the tip, obtuſe, ſcarcely twice the length of the calyx. Style obſcurely angular, the length of the ſtamens. Stigma umbilicate. Berry the ſize of a pea, covered with a lid, which does not ſeem to fall off ſpontaneouſly.—Eſcallon firſt found it in New Granada[u].

2. This is a low ſhrub, very much branched, leafy, ſmooth, and having the appearance of *Vaccinium*. Branches alternate, angular, ſomewhat flexuoſe, with a ſmooth, pale bark. Branchlets alternate, ſtraightiſh, leafy, one-flowered, green. Leaves only on the laſt ſhoots, deciduous, alternate, petioled, obovate, obtuſe, often retuſe, with a point, both ſurfaces even, obſcurely veined above, underneath pale, entirely without veins, having only a nerve running along the middle; attenuated at the baſe into a ſhort, channelled, keeled petiole, quite entire at the edge. No ſtipules or bractes. Flowers terminating, ſolitary, peduncled, upright, very handſome, milk white, with a violet-coloured germ. Peduncles ſhort, round, thickening at the tip, bent in, ſmooth. Diviſions of the calyx ſpreading, deltoid, ſomewhat fleſhy, ſmooth, pale underneath, coloured above. Petals ſpreading, obtuſe, three times the length of the calyx. Filaments broader at the baſe. Style columnar, ſhort. Berry ſmall, continuing through the winter, covered with a lid which is cut round horizontally near the calyx and at length falls off. All the parts of the fructification except the petals are only one-third of the ſize of thoſe in the foregoing ſpecies.

Commerſon found it in the ſtraits of Magellan; and Archib. Menzies in Terra del Fuego[w].]

ESCHALOT or Eſchalotte, [from Aſcalon, about which place it grows wild, this plant was called *Cepa Aſcalonica* and *Aſcalonitides*. The old Engliſh name was *Barren Onyons*, becauſe it ſeldom puts up any flowering ſtem.] See *Allium*.

ESCHYNOMENE. See *Mimoſa*.

ESCULUS. See *Quercus*.

ESPALIERS, are either rows of trees planted about a whole garden or plantation, or in hedges ſo as to incloſe quarters of ſeparate parts of a garden; they are trained up flat in a cloſe hedge, for the defence of tender plants againſt the violence and injury of wind and weather.

The moſt commonly received notion of Eſpaliers are hedges of fruit-trees, which are trained up regularly to a lattice of wood work, formed either of Aſh-poles, or ſquare long timbers cut out of Fir, &c. and it is of this ſort of Eſpalier that I ſhall treat in this place.

Eſpaliers of fruit-trees are commonly planted to ſurround the quarters of a kitchen-garden, for which purpoſe they are of admirable uſe and beauty; for by laying out the walks of this garden regularly, which are bounded on each ſide by theſe hedges, when they are handſomely managed, they have a wonderful effect in ſheltering the kitchen plants in the quarters, and alſo ſcreening them from the ſight of perſons in the walks; ſo that a kitchen-garden well laid out in this manner, and properly managed, will be equal to the fineſt regular parterre for beauty.

The trees chiefly planted for Eſpaliers are Apples, Pears, and ſome Plums; but the two former are moſtly uſed: ſome plant Eſpaliers of Apples grafted upon Paradiſe-ſtocks; but theſe being of humble growth, and a ſhort duration, are not ſo proper for this purpoſe, unleſs for very ſmall gardens; therefore I ſhould rather adviſe the having them upon Crab-ſtocks, or if in ſmaller gardens, where the trees cannot be allowed to grow ſo high, upon what the gardeners call the Dutch-ſtock; which will cauſe them to bear ſooner, and prevent their grow-

[t] Vahl. [u] Smith. [w] Smith.

ing too luxuriantly, and theſe will continue many years in vigour.

In chuſing the trees for an Eſpalier, endeavour as near as poſſible, to plant the ſeveral ſorts which are nearly of the ſame growth in one line, that the Eſpalier may be the more regular, and of an equal height, which greatly adds to their beauty; for if you plant trees which ſhoot very unequally in the ſame line, it will be impoſſible to make the Eſpalier regular: beſides, the diſtance of the trees muſt be in proportion to their growth; for ſome trees, viz. thoſe of a larger growth, ſhould be planted thirty or thirty-five feet aſunder; whereas thoſe of ſmaller growth, need not be above twenty-five feet diſtance from each other.

The width of the walks and borders between theſe Eſpaliers ſhould (in a large garden) be fourteen or ſixteen feet at leaſt; and if the trees are deſigned to be carried up pretty high, the diſtance ſhould be greater, that each ſide may receive the advantage of the ſun and air, which is abſolutely neceſſary, if you would have the fruit well taſted. And if your ground is ſo ſituated, that you are at full liberty which way to make the Eſpaliers, I would adviſe the placing the lines from the eaſt a little inclining to the ſouth, and toward the weſt a little inclining to the north, that the ſun may ſhine between the rows in the morning and evening when it is low; for in the middle of the day, when the ſun is advanced far above the horizon, it will ſhine over the tops of the Eſpaliers, and reach the ſurface of the earth about their roots, which is a matter of more conſequence than many people are aware of.

The ſorts of Apples proper for Eſpaliers, are the Golden Pippin, Nonpareil, Rennette Griſe, Aromatic Pippin, Holland Pippin, French Pippin, Wheelers' Ruſſet, Pile's Ruſſet, with ſome others. The ſeaſon for planting, and the method of pruning and training theſe trees, you will ſee under the articles of PRUNING, and PYRUS.

The ſorts of Pears proper for an Eſpalier, are chiefly the ſummer and autumn fruits, for ſome of the winter Pears ſeldom ſucceed well in an Eſpalier. Theſe trees, if deſigned for a ſtrong moiſt ſoil, ſhould be upon Quince-ſtocks; but if for a dry ſoil upon free-ſtocks. Their diſtance of planting muſt alſo be regulated by the growth of the trees, which are more unequal in Pears than Apples, and ſhould therefore be more carefully examined before they are planted. As for thoſe Pears upon free-ſtocks, the diſtance ſhould never be leſs than thirty feet for moderate growing trees: but for vigorous ſhooters, the ſpace of forty feet is little enough; eſpecially if the ſoil be ſtrong, in which caſe they ſhould be planted at a greater diſtance.

The particular ſorts of Pears I would recommend for an Eſpalier, are the Jargonelle, Blanquette, Poire ſans Peau, Summer Boncretien, Hamden's Bergamot, Autumn Bergamot, L'ambrette, Gros Rouſſelet, Chaunmontelle, Beurre du Roy, Le Marquis, Creſſane, with ſome others of leſs note; always remembering, that thoſe Pears which are of the melting kind, will do better in Eſpalier than the breaking Pears, which ſeldom ripen well on an Eſpalier; as alſo that many ſorts of Pears will ripen well on an Eſpalier in a warm ſoil and ſituation, which require a wall in other places; you ſhould alſo be careful of the ſtocks theſe are grafted on; for if the breaking Pears are grafted upon Quince-ſtocks, the fruit will be ſtony, but the melting Pears will be improved by them. As to the method of planting, ſee the article PYRUS; and for pruning and managing, ſee PRUNING.

I ſhall now give directions for making the Eſpalier, to which the trees are to be trained; but this ſhould not be done until the third year after the trees are planted; for while they are young, it will be ſufficient to drive a few ſhort ſtakes into the ground on each ſide of the trees, in a ſtraight line, to which the branches ſhould be faſtened in an horizontal poſition, as they are produced, in order to train them properly for the Eſpalier: which ſtakes may be placed nearer, or at a farther diſtance, according as the ſhoots produced may require; and theſe will be ſufficient for the three firſt years; for ſhould you frame the Eſpalier the firſt year the trees are planted, many of the ſtakes would rot before the Eſpalier is covered. The cheapeſt method to make theſe Eſpaliers is with Aſh-poles, of which you ſhould have two ſorts; one of the largeſt ſize, which contains thirteen poles in a bundle, and the other ſize thoſe of half a hundred. The firſt or largeſt ſized poles, ſhould be cut about ſeven feet and a half long; theſe are intended for upright ſtakes, and muſt be ſharpened at the largeſt end, that they may, with more eaſe, be driven into the ground; and if their bottoms are burned, or rubbed over with a proper compoſition, they may be preſerved a long time ſound; theſe ſhould be placed at a foot diſtance from each other in a direct line, and of an equal height, about ſix feet above ground; then you ſhould nail a row of ſtraight ſlender poles along upon the tops of the upright ſtakes, which will keep them exactly even, and continue to croſs the ſtakes with the ſmaller poles, and alſo with the tops which were cut off from the larger ſtakes, at about nine inches diſtance, row from row, from the top to the bottom of the ſtakes. Theſe rows of poles ſhould be faſtened with wire to the ſtakes, which if made of Fir, and painted over, will laſt a long time; and the largeſt end of the poles ſhould be cut flat, and nailed to the upright ſtakes, which will ſecure the Eſpalier almoſt as long as the poles will endure; whereas, if your faſtening is not ſtrong, the poles will be continually diſplaced with every ſtrong wind.

When your Eſpalier is thus framed, you muſt faſten the branches of the trees thereto either with ſmall Oſier-twigs, rope-yarn, or ſome ſuch binding, obſerving to train them in a horizontal poſition, and at equal diſtances; being careful not to croſs any of the branches, nor to lay them in too thick. The diſtance which ſhould be allowed for the branches of Pears and Apples, muſt be proportioned according to the ſize of their fruit; ſuch of them whoſe fruit is large, as the Summer Boncretien, Monſieur John, and Beurre du Roy Pears and the Runnet Griſe, Holland Pippin, French Pippin, and other large Apples ſhould have their branches fix or eight inches diſtance at leaſt; and to thoſe of leſſer growth, four or five inches will be ſufficient. But for farther directions, I ſhall refer to the articles of the ſeveral fruits: as alſo that of PRUNING, where theſe particulars with be ſufficiently explained.

But beſides this ſort of Eſpalier made with Aſh-poles, there is another ſort that is by many people preferred; which is framed with ſquare timbers cut to a proper ſize, according to the ſtrength thereof, or the expence the owner is willing to go to. Theſe, though they appear more ſightly, when well fixed and painted, are not of longer duration than one of the former, provided it is well made, and the upright poles are of ſufficient ſtrength; nor will they anſwer the purpoſe better, though they are vaſtly more expenſive; the greateſt beauty of an Eſpalier conſiſts in diſpoſing the branches of the trees; which, eſpecially in ſummer, when the leaves are on, entirely hide the frame. All expence, therefore, farther than what is neceſſary to ſecure the branches in a regular order, is needleſs.

Fruit-trees thus planted and well managed, are much preferable to thoſe trained up in any other figure: firſt, becauſe they take up very little room in a garden, and are not injurious to the crops in the quarters: ſecondly, becauſe the fruit is better taſted, the ſun and air having free acceſs to every part of the tree, and the dampneſs of the ground being quickly diſſipated: thirdly, becauſe the trees being kept low, and the branches faſtened to the Eſpalier, the fruit will not be ſo apt to be blown down by the wind.

DESCRIPTIONS, &c.

1. Root annual. Stem herbaceous, the thickness of a finger, four feet in height, upright, round, but angular at top, pubescent, hollow. Branches alternate, axillary, short, somewhat erect. Leaves alternate, longer than the intervals, lanceolate, acuminate, equally serrate, smooth, subpubescent underneath, veined, spreading very much, flat; the lowest opposite. Petioles very short, half-stem-clasping, channelled, subpubescent. Corymbs terminating, compound, three times shorter than the leaves, cylindric, streaked, upright, pubescent. Bractes few, subulate, bowed back, at the base of the peduncles. Flowers small, containing above twenty florets of a pale blue colour. Common calyx imbricate, longer than the flower, permanent; scales sharp, green, smoothish. Tube of the corollets cylindric, widening at top; segments of the border ovate, spreading. Seeds smooth, small.

It is a large plant, agreeing in stature with Baccharis or Conyza. The fructification corresponds in most circumstances with Eupatorium and Ageratum; but it differs materially from all these four genera, in having no down or feather to the seeds. It is also remarkable in having the florets distant; and in putting forth roots from the base of the stem, which is seldom the case in annual plants. The leaves smell very sweet.

Native of the East-Indies. It was sent to the Upsal garden by Professor David van Royen about the year 1760 or 1761, under the name of Eupatorium [a]. It was introduced here in 1776 by Mons. Thouin: and flowers in july and august [b].

2. Calyx subglobular, imbricate, with unequal scales, recurved, and patulous at the tip. Receptacle flat, with raised dots on it. Seeds small, uniform, ovate, narrower at bottom, rhomb-compressed, with angles at the sides, and one on the back, the rib white, but the interstices and the ventral plane of a pale testaceous colour. Pappus or crown margined or shaped like a bowl, a little more than half the length of the seed, subcartilaginous, snowy-white, shining, four-cornered, either quite entire, or obscurely four-toothed [c]. It is a very small plant, from the East-Indies. Linnæus doubts whether Vaillant's plant be the same. Gærtner separates this from Ethulia, with which he says it has nothing in common, except the calyx.

3. An annual plant, a hand in height. Stem upright, corymbed, smooth at bottom, pubescent at top, and branched: the primary branches shorter, sharply quadrangular. Leaves lanceolate, alternate, quite entire, somewhat fleshy, forming the angles of the stem by the bases running down on each side. Calyxes terminating, subsessile; the scales imbricate, subulate, extremely acuminate, standing out, purplish. Styles longer than the corollet [d].—Calyx subglobular, subsquarrose, scales oblong, petulous or recurved at the tip. Florets disform; those of the disk funnel-shaped, five-cleft, and rogynous, barren, fewer; in the ray awl-shaped, without teeth, female, fertile, very numerous. Receptacle flat, large, hollow-dotted. Seeds to the female flowers only, subturbinate, striated, minute, pale, bald, or without any crown [e]. Gærtner separates those which have a crown, under Vaillant's name of Sparganophorus.—Observed by König in the fields of Malabar.

4. Stems streaked, branched. Leaves alternate, sessile, lanceolate-linear, hoary, or very finely tomentose, like those of Lavender. Calyxes terminating, sessile, loose, somewhat leafy. Native of China [f].

5. Annual. Stem herbaceous, upright, hexagonal, brachiate. Leaves three-nerved, subpetioled, serrate, smooth. Racemes two or four, at the ends of the stems and branches, brachiate, on the upper side of which are sessile, narrow, yellow flowers, about five together, alternate, and supported by a subulate bracte. Seeds oblong, even, with a few streaks. Flowers small as in Milleria, but narrow.—Native of the East-Indies [g].

6. This rises generally to the height of two feet and a half, or more. Leaves alternate, oblong, entire. Flower-bunches interspersed with a few smaller ones, that rise between the common cups, as they stand compacted together at the axils of the leaves. Calyx bell-shaped, imbricate, with unequal, narrow, acuminate scales, from erect-spreading. Corollets nearly equal, the marginal ones trifid, the central ones four-parted. Germ oblong, angular, crowned with its proper calyx, which has about four little notches; style longer than the corolla; stigmas oblong, revolute. Receptacle tumid, dotted.

Native of Jamaica [h].

PROPAGATION AND CULTURE.

Most of these plants being annual, must be propagated by seeds; and coming from the East-Indies, must be kept in the stove. The first only has hitherto been cultivated in Europe.

EUCALYPTUS. (Ευ καλυπτος, *bene tectus, opertus; well covered. So named from the perianth being covered with a remarkable veil or lid.*)

DESCRIPTION, &c.

1. This is a very tall tree, growing to the height of more than an hundred feet, and above thirty in circumference: the bark is ſmooth, like that of the poplar: the younger branches are long and ſlender, angulated near the top, but as they grow older the angles diſappear. The leaves are alternate, lanceolate, pointed, very entire, ſmooth on both ſides, and remarkably unequal or oblique at their baſe: the veins are alternate, and not very conſpicuous: the whole ſurface of both ſides of the leaves is marked with numerous minute reſinous ſpots, in which an eſſential oil reſides: the footſtalks are about half an inch in length, round on the under ſide, angular above, quite ſmooth. The flowers have not been fully examined, but the capſules are ſuppoſed to grow in cluſters from ſix to eight in each, ſeſſile and conglomerated: each is about the ſize of a hawthorn berry, globular, but as it were cut off at the top, and of a dark brown colour: the ſeeds numerous, ſmall, and angular. N. B. It is not clear that the above is really the ſame ſpecies with the E. obliqua of L'Heritier. The deſcription is taken from Mr. White's Voyage, where it is named E. piperita.

2. This is a large and lofty tree, much exceeding the Engliſh oak in ſize: the wood is brittle, and contains a large quantity of reſinous gum: the flowers grow in little cluſters, or rather umbels, about ten in each, and every flower has its proper partial footſtalk, about a quarter of an inch in length, beſides the general one: the general foot-ſtalk is remarkably compreſſed, and the partial ones in ſome degree: the flowers are yellowiſh, and of a ſingular ſtructure: the calyx is hemiſpherical, perfectly entire on the margin, and afterwards becomes the capſule: on the top of the calyx, rather within the margin, ſtands a conical pointed calyptra, which is of the ſame colour with the calyx, and about as long as that and the calyx taken together: this calyptra, which is the eſſential mark of the genus, and differs from that of the E. obliqua of L'Heritier, only in being conical and acute inſtead of hemiſpherical, is perfectly entire, and never ſplits or divides, though it is analogous to the corolla of other plants: when it is removed, we perceive a great number of red ſtamina ſtanding in a conical maſs: the anthers are ſmall and red, and in the centre is a ſingle ſtyle, terminated by a blunt ſtigma: the ſtamens are very reſinous and aromatic: the germ appears, when cut acroſs, to be divided into three cells; each containing the rudiments of one or more ſeeds. On making inciſions into the trunk of this tree, large quantities of red reſinous juice are obtained; ſometimes more than ſixty gallons from a ſingle tree. When dried this juice becomes a powerfully aſtringent gum-reſin, much reſembling that known in the ſhops by the name of Kino, and for all medical purpoſes full as efficacious. Mr. White, the chief ſurgeon to our ſettlement at Botany Bay, adminiſtered it to a great number of patients in the dyſentery, and found it eminently ſerviceable, ſo as not to fail in a ſingle inſtance. This gum-reſin diſſolves almoſt entirely in ſpirit of wine, to which it gives a blood-red tincture: water diſſolves about a ſixth part only, and the watery ſolution is of a bright red: both theſe ſolutions are powerfully aſtringent.

DESCRIPTION, &c.

This is a branching tree. Leaves alternate, ſubpetioled, obovate, quite entire, obtuſe, ſmooth, perennial. Racemes of flowers from the axils of the upper leaves, ſimple, nodding, hardly the length of the leaves[a].

Monſ. L'Heritier remarks that ſpecimens of this and Celaſtrus corniculatus, when in fruit, are ſo much alike as one egg is to another, and that from this circumſtance, before he was acquainted with the flower, he took this for that.—See Celaſtrus corniculatus.

Native of the Cape of Good Hope. Introduced here in 1722, by Mr. Thomas Knowlton. It flowers in november and december[b].

3. Eucomis undulata. *Waved-leaved Eucomis* or *Fritillary.*
Ait. hort. kew. 1. 433.
Scape cylindric, leaves ovate-oblong, waved, spreading, the leaves of the coma almost as long as the raceme.

4. Eucomis punctata. *Spotted Eucomis.*
L'Herit. sert. angl. 18. *t.* 18. *Ait. hort. kew.* 1. 433.
Asphodelus comosus. *Houtt. nat. hist.* 12. 336. *t.* 83.
Scape cylindric, leaves oblong-lanceolate, channelled, spreading, leaves of the coma short, racemes very long.

DESCRIPTIONS, *&c.*

1. The leafing is that of Massonia. Leaves ovate, acuminate, marked with lines underneath, the veins confluent at the tip[a]. Native of the Cape of Good Hope. It flowers in may. Introduced in 1774, by Mr. Francis Masson[b].]

2. Root tuberous, from which arise in the autumn six or eight obtuse leaves, near five inches long, and two broad towards the top, growing narrower at their base, crenated on their borders, lying flat on the ground, and continuing all the winter. In the spring arises the flower-stalk in the centre of the leaves, about six inches high, naked at the bottom; but the upper part is surrounded by bell-shaped flowers, of a greenish colour, appearing in april. The leaves decay in june.

[Native of the Cape of Good Hope. Cultivated in the Eltham garden, to which it was sent by Mr. Blathwaite of Dirham in Gloucestershire[c].—And before that, in 1709, by the Dochess of Beaufort, at Badminton[d]; from whose garden probably Mr. Blathwaite had it.]

3. The leaves of this are more than a foot long, broad at their base, but narrowed to the top, where they end in acute points. The flower-stalk rises higher than that of the preceding; the flowers are of the same shape and colour, but seldom appear till august. It was raised by Mr. Miller from seeds sent him from the Cape of Good Hope.

[3. Native of the Cape of Good Hope. It flowers from march to may. Introduced about 1760 by Mr. Miller[e].

4. Native of the Cape of Good Hope. It flowers in july. Introduced in 1783, by Mr. John Græfer[h]. This is the largest species; the second is of a middle size, and the first is small[i].

PROPAGATION AND CULTURE.

These plants are to be managed in the same way with other Cape bulbs.

Leaves crenate, racemes very long, pomes ovate, quadrangular.

8. Eugenia sessiliflora.
Vahl. symb. 3. 64.
Flowers lateral, sessile, leaves oblong, quite entire, shining, dotted underneath.

9. Eugenia punctata.
Vahl. symb. 3. 65.
Leaves oblong, dotted on both sides, peduncles opposite three-flowered, the length of the leaves.

10. Eugenia nervoſa.
Lour. cochinch. 308.
Leaves quite entire, flowers heaped, terminating, berries globular nerved.

11. Eugenia corticoſa.
Lour. cochinch. 308.
Leaves ovate, acuminate, racemed, corymbed, filaments very ſhort.

DESCRIPTIONS, *&c.*

Theſe are trees or ſhrubs, all natives of the Eaſt or Weſt-Indies. The flowers are borne on peduncles, proceeding either from the axils or ends of the branches, either ſingly, or many together in a trichotomous ſtructure[a]. The fruit in ſome ſorts ſeems to be rather a berry than a drupe; and in the 6th and 7th is called a pome.

1. This riſes with a tree-like ſtem from twenty to thirty feet high, covered with a brown bark, and ſending out many branches. Leaves oblong, ending in acute points, oppoſite; when young of a bright purple colour, but as they grow older becoming of a light green. The flowers are produced on the ſides of the branches; every peduncle branching into three or four others, each of which ſupports one flower. Fruit ſucculent, irregularly ſhaped, and incloſing a ſingle nut. Loureiro calls it a berry: it is of a roundiſh form, commonly obtuſely quadrangular; ſometimes it is ovate; in ſize it is an inch and half in diameter, fleſhy, very ſweet, ſmelling like the roſe, not very juicy; covered with a thin, ſhining, yelloviſh ſkin; and containing commonly one ſeed, which is large, roundiſh, ſoftiſh, not bony or horny. The fruit is very agreeable to the taſte, ſmell, and ſight, and is eſteemed wholeſome.—Forſter deſcribes it as whitiſh, tinged with roſe-colour, pear-ſhaped, and ſometimes as big as the fiſt, but uſually much ſmaller. It is very common in moſt of the iſlands in the South Sea, and is cultivated almoſt every where between the tropics.—Mr. Miller cultivated it here in 1768[b].] He ſays that he received it from Dr. Heberden, with ſome other plants, which were ſent by his brother from Braſil.

2. This riſes to the ſame height, but the leaves are longer and narrower. Flowers moſtly terminating, but ſome come out from the ſides. Fruit ſmaller, rounder, and not ſo much eſteemed.

[Leaves oppoſite, petioled, the lower oval, the upper lanceolate, and very long[c]. Flower greeniſh yellow. Fruit pearl-ſhaped, two inches long, white and red, having no ſmell[d].

Native of the Eaſt-Indies and Cochinchina. It flowers from may to july. Cultivated in 1768 by Mr. Miller[b].

3. This is an upright tree twenty feet high, in appearance not unlike a Pear tree. Leaves lanceolate-ovate, acuminate and ſickle-ſhaped at the end, bright green, ſhining, from three to four inches long, oppoſite, on ſhort petioles. Peduncles one-flowered, above an inch long, aggregate. Calyx deeply four-parted. Petals white. Fruit globular, at firſt green, then paſſing through the different ſhades of yellow as it ripens, till at length it becomes ſcarlet; it is ſcarcely half an inch in diameter, the ſkin is thin, and the pulp is ſoft, ſweet and red. The ſeed is large and globular. Native of Martinico, where it is called *Goyavier baſtard*. It flowers in october, and bears fruit in december and january[e].

4. Peduncles ſolitary. Flowers white; fruit bright red, ſoft, ſlightly grooved, and having a ſweet ſmell. It was firſt brought from Goa, and cultivated in the Grand Duke's garden near Florence; whence it came into the public botanic garden of Florence and Piſa about the year 1718[b].

5. The younger branches are angular. The leaves are numerous, oppoſite, ſubpetioled, glittering, leathery, ſometimes but ſeldom emarginate. Peduncles axillary, one, two or three[b], ſlender, an inch in length. Fruit globular, ſucculent, incloſing a ſingle ſhining membranaceous nut, having one ſeed in it. Native of Cayenne, where it is called by the French *Ceriſier de Cayenne*[f].

6. Leaves at the ends of the branches, exactly like thoſe of the Horſe-Cheſnut, obovate, ſharpiſh, very finely toothed. Raceme ſimple, very long. Flowers ſmall, with longiſh ſtamens and piſtils[a]. Loureiro ſays, it is a large tree with ſpreading branches.—Leaves large, ſmooth, ſcattered, on long petioles. Flowers reddiſh, ſeſſile, on racemes often two feet long, and pendulous. Calyx bell-ſhaped, with roundiſh ſegments. Petals ſmall, roundiſh, converging. Filaments filiform, very long, with roundiſh anthers. Germ turbinate-round: ſtyle awl-ſhaped, longer than the ſtamens. Berry oblong, three inches in length, ſharpiſh at both ends, quadrangular, with ſharp angles, juiceleſs, corticoſe, ſomewhat wrinkled, browniſh yellow; incloſing one large ovate ſmooth farinaceous ſeed.

Native of the Eaſt-Indies, and of Cochinchina.

7. Peduncles ſimple, longer than the leaves, pendulous. Pomes rounded, without any ſharp angles[c]. Native not only of India, but of New Caledonia in the South Seas.

Juſſieu refers the two laſt ſpecies to other genera; the 6th to *Stravadium*, and this to *Butonica*: both having alternate leaves, and many flowers together in racemes.

8. Branches round, ſmooth, covered with an aſh-coloured bark, leafy at top, warted below. Leaves oppoſite, on very ſhort petioles, ſometimes two inches long, and frequently an inch and half broad, the edges a little turned back, netted-veined on both ſides, very ſmooth, the upper ſurface ſhining and not dotted, the lower paler, with numerous browniſh dots ſcattered over it. Flowers below the leaves, ſolitary or ſeveral, oppoſite. Calyx coriaceous, with oblong leaflets, hoary on the outſide, dotted with brown. Fruit the ſize of a Plum, globular, dotted. Obſerved in the iſland of Santa Cruz by Weſt.

9. Branches round, alternate, aſh-coloured at bottom, purpliſh at top, having raiſed dots ſcattered over them. Leaves oppoſite, an inch or more in length, bluntiſh, ſmooth, rigid, flat, quite entire, paler underneath, on ſhort petioles; when young they are ſilky. Peduncles axillary, ſolitary, dotted. The two lateral flowers pedicelled, the middle one ſeſſile. There are two briſtle-ſhaped bractes at the baſe of the lateral ones. Segments of the calyx five, rounded, dotted. Petals, when magnified, appearing to be very finely ciliate.

Obſerved in the iſland of Santa Cruz by von Rohr and Weſt[h].

Vahl doubts whether it be any thing more than a variety of Myrtus fragrans, with which it agrees in many circumſtances. It differs only in having the peduncles conſtantly axillary and three-flowered, not terminating and three-parted, with three-flowered pedicels, as in Myrtus fragrans: the leaves alſo are on longer petioles. It ſeems to differ from Eug. guianenſis of Aublet in having the peduncles the ſame length with the leaves, and larger flowers.

10. This is a large tree, with ſpreading branches. Leaves lanceolate, ſmooth. Flowers white, on one-flowered peduncles. Calyx large. Petals roundiſh, ſmall, quickly deciduous. Filaments linear, more than a hundred, three times as long as the petals, ſpreading out wide into a globular head: with ſmall, nodding anthers. Style awl-ſhaped longer than the ſtamens, with a ſharp ſtigma. Berry globular, an inch in diameter, nerved, ſmooth, corticoſe, browniſh red; incloſing one globular ſeed, in many angular pieces, nearly equal in ſize, and eaſily ſeparable.

11. This alſo is a large tree with ſpreading branches, covered with a thick cloven bark, having ſomething of an aromatic flavour. Leaves quite entire, ſmooth, ſuboppoſite. Flowers reddiſh-white, ſmall, numerous, ſubterminating. Calyx goblet-ſhaped, ſubtruncate. Petals ſmall, roundiſh, cloſed.

[i] Jacquin. [k] Linn. zeyl. [l] Ibid. [m] Vahl.

Filaments

Filaments twenty, awl-shaped, shorter than the corolla, placed near the edge of the calyx; anthers roundish, very small. Berry only a quarter of an inch in diameter, subturbinate, smooth, blackish; inclosing one roundish sostish seed.

This and the preceding are natives of Cochinchina in woods[a].

Jacquin has another species, which he names Eugenia carthagenensis, with two varieties of it—barbuensis and myrtifolia.]

PROPAGATION AND CULTURE.

Set the stones, fresh from their places of natural growth, in small pots filled with light earth: plunge them in a hot-bed, observing to keep the earth moist, but not wet. In about six weeks the plants will appear; when about four inches high, separate them carefully, plant each in a small pot, plunge them in the hot-bed again, and shade them carefully till they have taken new root. Treat them in the same way as other tender plants from the same countries, keeping them plunged in the tan-bed, and in winter watering them sparingly.

Leaves lanceolate, sessile, silky underneath, peduncles short, one-flowered.

DESCRIPTIONS, &c.

1. From a small stringy, fibrous, annual root, spring long, trailing stalks, taking root here and there where they touch the ground, and putting forth alternately at small unequal distances leaves almost round, like those of *Lysimachia tenella*, three quarters of an inch long, and an inch broad, having a small notch at the end, and on petioles a quarter of an inch in length, and of a brown colour. Flowers axillary, on short peduncles, of a light blue colour; (Swartz says, white.) Legume brown, containing two or three brown seeds[b]. Browne observes that the flowers are deeply crenated. Jussieu affirms, that the styles are two, and bifid; and that the plant is not milky. According to Swartz, the styles are three or four; and the capsule three or four-celled, and three or four-valved.

Native of Jamaica and Barbadoes. Common also in the dry plains of other islands in the West-Indies.

2. Native of the East-Indies.

3. This is a little annual plant, with a creeping root. The stems, leaves, petioles and peduncles are covered with rufous hairs. Leaves alternate, roundish, on a short petiole. Flowers axillary, solitary, on long peduncles. Corolla blue, large in proportion to the plant. In Ceylon it has the name of *Wishnugarandi*, from the Malabar deity *Wishnu*, and *Garandi*, which signifies the dysentery. It is reputed to be a sovereign remedy in that disorder[c].

Native of the East-Indies. Introduced in 1771, by Monf. Richard. It flowers in june and july[d].

4. Annual. Stems filiform, creeping. Leaves petioled, smooth, waved about the edge; petioles muricate underneath. Flowers axillary, solitary, small. Peduncles the length of the petioles. Native of the East-Indies[e].

5. This whole plant has the appearance of a very fine sort of flax. It seldom rises above ten or fourteen inches. The stalk is generally simple, or but very little divided, slender and upright. The leaves are narrow and few; they each throw out a long and delicate peduncle from their axils, furnished with a very small exterior two-leaved cup about the middle. The styles are two, and bifid. The capsules are divided into two or four cells, and contain many seeds. In the low lands of Jamaica[f]. It is an annual; flowers in august and september; and was introduced in 1782, by Mr. Francis Masson[g].

6. The stem of this is twining. Native of the East-Indies[h].

7. According to Browne, this is so extremely like the linifolius, that they are hardly to be distinguished without great attention. The flower-stalks are very short in this, the cups single, and every flower furnished with four styles. Native of Jamaica, in the low lands.

PROPAGATION AND CULTURE.

These are all stove plants, to be cultivated and treated as the tender sorts of Convolvulus from the same countries.

DESCRIPTIONS, &c.

The difficulty of giving ſignificant and permanent ſpecific or trivial names, is apparent from this genus. When two ſpecies only were known, they might well be diſtinguiſhed by the titles *europæus* and *americanus*; but now that we know three European and two American ſpecies, this diſtinction is inſufficient, and very abſurd. The ſame may be ſaid of Thunberg's title *japonicus*: and he ought to have done better, becauſe he knew that there were two Japaneſe ſpecies. I acknowledge the difficulty of giving ſignificant trivial names to be great; and I leave them as I find them, being unwilling to increaſe that confuſion which neceſſarily ariſes from the prodigious number of plants which the induſtry of later botaniſts has diſcovered.

Theſe are trees or ſhrubs. The ſmaller branches or twigs four-cornered. The leaves oppoſite, ſcarcely ſtipulaceous. The peduncles axillary, ſolitary, oppoſite, one-flowered or elſe many-flowered, diſpoſed in unbels[a].]

1. The common Spindle-tree, when growing in hedges, is ſeldom ſeen of any conſiderable ſize, but is a ſhrub; if planted ſingle, however, and properly trained, it will have a ſtrong woody ſtem, and riſe more than twenty feet high, dividing into many branches. Leaves lanceolate, about three inches long, and an inch and quarter broad in the middle, oppoſite, entire, of a deep green colour. The flowers come out at the end of may, or the beginning of june, in ſmall bunches, from the ſide of the ſtalks on ſlender peduncles. The petals are whitiſh, and ſpread in form of a croſs.

[Though moſt of the flowers have four ſtamens, a four-parted calyx, and four petals to the corolla; yet it may be ranged in this claſs, with its congeners, from the primary flower, which has five ſtamens, a five-parted calyx, and five petals[b]. The capſule is turbinate, ſwelling out like a cuſhion, or the old-faſhioned clerical cap, four-grooved; barked with a ſoft red membrane, coriaceous, four-celled and four-valved. Partitions faſtened to the middle groove of the valves. Seeds fixed, without any receptacle to the central angle of the cells; they are ſolitary, or very rarely in pairs, ovate-globular, ſmooth, involved in a fleſhy-ſpongy aril, which is perforated in the part oppoſite to the navel, fixed to the dorſal band of the ſeed, and ſaffron-coloured; the ſeeds are pale fleſh or roſe-coloured[c].] The fruit ripens in october, at which time the ſeed-veſſels ſpread open and expoſe the ſeeds, which being of a beautiful red colour, theſe ſhrubs make then a good appearance.

[From its uſe for ſkewers it has the name of *Prick-wood*, and is called by Gerarde *Prick Timber tree*. It is called alſo *Louſe Berry*, *Dogwood* and *Gatteridge Tree*, by which latter names it is confounded with *Cornus ſanguinea*.

In German it is named *Spindelbaum*. In Swediſh *Alfter*. In Daniſh *Beenved*. In Italian *Fuſaggine*. In Spaniſh *Benetero*; *bonete de clerigo*. In Portugueze *Barrete de clerigo*. In Ruſſian *Mereſkletiana*, *Kiſtianka*, *Swoida*, *Sedlini Bereſdren*.

The wood is ſaid to be uſed by the muſical inſtrument makers. For ſkewers and toothpicks the branches ſhould be cut when the ſhrub is in bloſſom, for it is then tough, and not eaſily broken; in that ſtate it is alſo uſed by watch-makers, for cleaning watches. According to Linneus, kine, goats

[a] Juſſieu. [b] Linn. [c] Gærtner.

and

and ſheep eat it, but horſes refuſe it. No animal, however, ſeems to browze upon it but the goat. The berries are ſaid to be fatal to ſheep: they vomit and purge violently; powdered and ſprinkled upon the hair, they deſtroy lice[4].]

2. This riſes with a ſtronger ſtem than the firſt, and grows to a larger ſize. The leaves are ovate-lanceolate, about four inches long, and two broad in the middle, oppoſite, entire, light green, on ſhort foot-ſtalks. The flowers come out from the ſide of the branches, upon very ſlender peduncles, two inches and a half long, branching out into a looſe bunch, and the flowers on ſeparate pedicels. Petals five, at firſt white, but changing to purple. The ſame number predominates in the other parts of the fructification. The fruit is much larger than that of the common ſort, and the peduncles being weak, it always hangs down. Native of Auſtria, Hungary, and moſt of the ſouthern parts of Europe. This was ſeldom ſeen in England, till Mr. Miller procured it from France; and it is now become very common in the nurſeries.

[3. This differs from the two former in having the ſtem and branches warted, the upper ſurface of the petals covered with a pile conſiſting of very ſmall teats; the anthers rounded and placed upon their pyramidal filaments like the cap of a muſhroom—a raiſed tubercle ſupporting each filament—the receptacle variegated, with red dots—no ſtyle, but inſtead of it a ſtigma like a bladder—the capſule more flatted at top, the ſurface a little wrinkled, and as broad as long—the ſeeds half black[5]. Native of Auſtria and Carniola.—Cultivated here in 1763 by Mr. James Gordon; and flowering in may and june[6].

4. This is a native of the northern parts of Aſia, and is a ſhrub about ſix feet high, with an aſh-coloured bark, ſmooth, and free from tubercles: the branches are round, and a little compreſſed at their extremities: the leaves are oblong-lanceolate, ſmooth on both ſides, veiny on the back, and ſtand oppoſite; they are very finely ſerrated on the edges, where they are of a purple tinge, as are alſo the foot-ſtalks: the common peduncles are biflorous, ſlender and branchy; the proper ones red. All the flowers, (which are dark purple) are conſtantly tetrandrous. The ſtyles are greeniſh, and the anthers yellow[7].

Introduced in 1756, by Meſſrs. Kennedy and Lee[8].]

5. This riſes with a ſhrubby ſtalk to the height of eight or ten feet, dividing into many branches, which come out oppoſite from the joints of the ſtem. Leaves lanceolate, two inches long, and about three quarters of an inch broad in the middle, ending in acute points; they are oppoſite, and continue green all the year. The flowers are produced at the ends of the branches, and alſo from the ſides, in ſmall cluſters; and are ſucceeded by round capſules, which are cloſely armed with rough protuberances. It flowers in july, but ſeldom produces ripe fruit in England.

This being an evergreen ſhrub, it merits a place in every curious garden, and particularly in all plantations. There is a variety in the nurſeries with variegated leaves.

[It was cultivated in 1713, by Biſhop Compton[9].

6. Stem ſhrubby, upright, leafleſs, branched, ſcarce a fathom in height. Branches alternate, round, upright, round, leafleſs. Branchlets alternate, upright, green, ſmooth, leafy. Leaves aggregate, petioled, ſhining above, pale underneath, netted, bent down at the edge, upright, thickiſh, from an inch to two inches in length, oblique, ſmooth. Petioles compreſſed, pale, half an inch long. Flowers at the ends of the branchlets, aggregate in a kind of umbel, upright. Peduncles round, one-flowered, ſeldom divided, pubeſcent, twice the length of the petioles. Calyx ſeldom four-cleft, pubeſcent, green, upright, cloſed, four times ſhorter than the corolla; diviſions lanceolate, bluntiſh, keeled. Petals five, ſeldom ſix, white, ſmelling like orange flowers, oblong-ovate, blunt, entire, patulous. Stamens ſeldom five. Capſule ovate, blunt, crowned with the permanent ſtyle, ſmooth, three-furrowed, three-valved, ſeldom four-valved, very rately five-valved and five-furrowed. Seeds about four within each valve, ovate, angular, red, involved in a viſcid aril, within white. The whole plant is ſomewhat milky. Native of Japan, where it flowers in may[10].

7. Stem ſhrubby, ſtrict, aſh-coloured, naked, a fathom in height. Branches oppoſite, from upright ſpreading, green, but little leafy. Branchlets decuſſate, leafy, ſhort, green. Leaves on the outmoſt branches, oppoſite, approximate, petioled, ſerratures obtuſe, entire at bottom, thick, paler underneath, nerved, ſmooth, from erect ſpreading, an inch in length. Petiole ſemicylindric, ſmooth, a line long. Flowers axillary, panicled. Panicle trichotomous, decompound, divaricate, ſubbaſtigiate. Peduncle and pedicels angular, ſmooth, compreſſed. Calyx four-leaved, permanent, inferior; diviſions broad-ovate, obtuſe, concave, ſmooth, half the length of the corolla, pale green. Corolla four-petalled, white, patulous; petals rounded, concave, entire, a line in length. Stamens four. Capſule ſubglobular, four-grooved, ſmooth, four-valved, four-celled; the ſtyle and calyx permanent. Seeds four, oblong, the outer coat red, within white, in the centre green. Sometimes one of the ſeeds is abortive. Sometimes alſo the calyx is three-leaved, the germ three-ſided, and the capſule three-celled and three-furrowed.—It varies with leaves ſpotted with white. The flowers appear in june and july, and the fruit ripens in november and december.—Native of Japan[11].]

8. Stem herbaceous, long, climbing by tendrils. Leaves cordate, three-lobed, the middle lobe acute, the ſide ones obtuſe, toothletted, ſharp. Flowers white. Calyx five-cleft, ſpreading. Petals five, oblong-ovate, ſpreading, longer than the calyx. Berry ſuperior, ovate, attenuated to both ends, ten-cornered, one-celled, valveleſs, containing many ovate compreſſed ſeeds, covered by a ſucculent calyptre. Native of China, beyond the ſuburbs of Canton.

It does not agree very well with this genus, but may remain here till a better place be found for it[12].]

PROPAGATION AND CULTURE.

1—4. The four firſt ſorts may be propagated either by ſeeds, or layers; if by ſeeds they ſhould be ſown in autumn, ſoon after they are ripe; then the plants will come up the ſpring following; but if the ſeeds are not ſown till ſpring, the plants will not appear till the following ſpring, whereby a whole year is loſt. The ſeeds ſhould be ſown upon a ſhady border, where they will ſucceed better than when they are more expoſed to the ſun. When the plants come up, they will require no other care but to keep them clean from weeds till the following autumn, when, as ſoon as their leaves decay, the plants ſhould be taken up and tranſplanted into a nurſery, in rows two feet diſtant, and the plants one foot aſunder in the rows; in this place they may remain two years, and then they may be removed to the places where they are to remain.

When theſe are propagated by layers, the young ſhoots ſhould be laid down in autumn; and if the joint which is laid deepeſt in the ground is ſlit, as is practiſed for Carnations, it will cauſe them to put out roots much ſooner than they otherwiſe would do; theſe layers will be ſufficiently rooted in one year to bear tranſplanting, when they ſhould be taken from the old plants, and treated in the ſame way as the ſeedlings. The cuttings of theſe ſorts, planted in a ſhady border, will take root, but they ſhould be planted in autumn, as ſoon as their leaves begin to fall; they ſhould be the ſhoots of the

[4] Withering. [5] Jacquin. [6] Scopoli. [7] Hort. kew. [8] Hort. kew. [9] Ibid. [10] Thunberg. [11] Ibid. [12] Loureiro.

same year, with a knot of the former year at bottom.

5. The fifth sort, which grows naturally in North America, is so hardy as rarely to suffer by cold in England, provided it is not planted in places very much exposed. This may be propagated by laying down the young branches in the autumn, observing to tongue them in the same manner as is practised in laying of Carnations: these will have made good roots in one year, when they may be cut from the old plants, and planted in a nursery for two years to get strength; after which, they should be planted where they are designed to remain.

[6, 7, 8. Have not yet been introduced into cultivation.

SPECIES.

1. Euparea amœna.

Soland. Mss. t. 50. *f.* 5. *Gærtn. fruct.* 1. 230.

DESCRIPTION, *&c.*

This is a procumbent plant, having the appearance of Nummularia, but only one fourth of the size. The flowers have the colour of those of Anagallis phœnicea or Pimpernel, but are many-petalled. The fruit, which Gærtner in one place calls a capsule, and in another a juiceless berry, however it be pressed, will not open with regular valves; it is therefore nearly allied to Trientalis. The seeds have a navel in the belly opposite to the embryo.

Native of New Holland[a], and Terra del Fuego.

Lin. ſpec. 1173. *Reich.* 3. 717. *Cold. noveb.* 180. *Gron. virg.* 119. *Corn. canad. t.* 72. *Mor. t.* 13. *f.* 4. *Lour. cochinch.* 487. *Gærtn. fruct.* 2. 401.
Leaves in fours, ſcabrous, lanceolate-ovate, unequally ſerrate, petioled, wrinkled.

[25. Eupatorium diffuſum.
Vahl ſymb. 94.
Leaves ovate, ſerrate, three-nerved, panicle very much branched and diffuſed.

26. Eupatorium nervoſum.
Swartz prodr. 111.
Leaves elliptic-lanceolate, attenuated, toothed, triple-nerved, ſmooth on both ſides, calyxes many-flowered.

27. Eupatorium rigidum.
Swartz prodr. 111.
Leaves petioled, ovate, acute, ſerrate-toothed, rigid, rugged underneath, ſtem ſubherbaceous.]

28. Eupatorium maculatum. *Spotted Hemp-Agrimony.*
Lin. ſpec. 1174. *ſyſt.* 736. *Reich.* 3. 718. *amæn.* 5. 288. *hort. cliff.* 396. *Herm. par. t.* 158. *Mor. t.* 18. *f.* 3. *Raii ſuppl.* 187. 15.
Leaves in threes, ſomewhat tomentoſe, lanceolate, equally ſerrate, veined, petioled.

[29. Eupatorium auriculatum.
Vahl ſymb. 3. 95. *t.* 72.

E tomentoſum. *Lamarck encycl.* 2. 407.

Leaves ovate, toothletted, tomentoſe underneath, petioles eared, ſtem climbing, flowers in ſpikes.

30. Eupatorium molle.
Swartz prodr. 111. *Aubl. guian.* 800. 3. (Ageratum).
Leaves petioled, cordate, acute, ſubſerrate, pubeſcent, ſtem herbaceous tomentoſe.

31. Eupatorium villoſum.
Swartz prodr. 111. *Vahl ſymb.* 3. 94. *Sloan. jam.* 1. 257. *t.* 161. *f.* 1. (Conyza).
Leaves oppoſite, decuſſated, ovate, ſubſerrate, beneath villoſe-tomentoſe, calyxes eight to fifteen-flowered, ſtem ſhrubby.

32. Eupatorium cordifolium.
Swartz prodr. 111.
Leaves cordate, ſerrate, tomentoſe-hirſute underneath, petioles very ſhort, corymbs ſubſeſſile, calyxes ſquarroſe, ſtem ſhrubby.

33. Eupatorium montanum.
Swartz prodr. 111.
Leaves cordate, acute, toothletted, petioled, rugged, hirſute underneath, corymbs much ſpreading, ſtem ſhrubby.

34. Eupatorium caneſcens.
Vahl ſymb. 3. 95. *t.* 73.
Hoary, leaves ovate, ſublobed and entire, underneath very ſoft, and three-nerved, corymbs ſimple.

35. Eupatorium ſcabrum.
Lin. ſyſt. 736. *ſuppl.* 354. *Smith. ic. ined.* 3. *t.* 67.
Villoſe; leaves oppoſite, petioled, ovate, moſtly entire, wrinkled, ſcabrous on the upper ſurface.]
* * * * *Calyxes with fifteen or more floſcules.*

36. Eupatorium perfoliatum. *Perfoliate Hemp-Agrimony.*

Leaves deltoid, toothed at bottom, tomentoſe underneath, calyxes many-flowered.

[43. Eupatorium triplinerve.
Vahl ſymb. 3. 97.
Leaves lanceolate, triple-nerved, quite entire, ſmooth.

44. Eupatorium ivæfolium.
Lin. ſpec. 1174. *Reich.* 3. 720. *amæn.* 5. 405
Swartz obſ. 301.

Leaves

Leaves narrow-lanceolate, three-nerved, ſubſerrate; calyxes ſquarroſe, many-flowered.

45. Eupatorium urticæfolium.
Nettle-leaved Hemp-Agrimony.
Lin. ſyſt. 736. *ſuppl.* 354. *Smith. ic. ined.* 3. *t.* 68.

Hiſpid; leaves petioled, cordate, goſh-ſerrate, panicle terminating, calyxes many-flowered, awl-ſhaped, ſomewhat pungent.

46. Eupatorium ſtoechadiſolium.
Lin. ſyſt. 736. *ſuppl.* 355. *Smith. ic. ined.* 3. *t.* 69.

Tomentoſe; leaves petioled, linear, crenate, hoary underneath; panicle terminating.

47. Eupatorium microphyllum.
Lin. ſyſt. 737. *ſuppl.* 355. *Smith. ic. ined.* 3. *t.* 70.

Leaves triangular-ovate, with nine notches, tomentoſe and veined underneath, panicle conglomerate, terminating, peduncle elongated.

48. Eupatorium ſquarroſum.
Cavan. ic. hiſp. 66. *n.* 107. *t.* 98.

Leaves ſubcordate, ovate-acute, ſerrate, calyxes ſquarroſe.

49. Eupatorium ſinuatum.
Lour. cochinch. 487.

Leaves ovate, ſinuate, hairy, alternate, calyxes eight-flowered, or thereabouts.

DESCRIPTIONS, *&c.*

Theſe are moſtly tall growing perennial herbaceous plants; the greater part of the old ſorts are natives of North America; many, however, of South America and the Weſt Indies; whence come moſt of the new ſorts: ſeveral are found wild in the Eaſt-Indies, and one only in Europe. The two firſt and a few other ſpecies are ſhrubby. Some have weak ſtems, and ſupport themſelves by twining. The leaves in moſt of the ſpecies are oppoſite; but in a few they are verticilled or alternate. The flowers are moſt frequently in corymbs at the ends of the ſtem and branches, or elſe axillary; the predominant colour of the corolla is purple; ſome, however, are white.

1. This riſes to the height of nine and ten feet or more: it has a moderately thick woody ſtem; and throws out its branches in a pretty open poſition[a]. This ſhrub is frequent in the lower hills of Liguanea, in Jamaica.

Dr. Patrick Browne thought it generically diſtinct from *Eupatorium*, and therefore gave it the name of *Dillea*.

It flowers here in auguſt; and was introduced in 1773, by Monſ. Richard[b].

Swartz deſcribes this ſhrub as a fathom in height, with a branched even ſtem, and long ſmoother branches. Leaves oppoſite and decuſſated, broad-lanceolate, four or five inches long, ſhining, on petioles of a middling length. Corymbs terminating; branchlets oppoſite, decuſſated, ſubdiviſtigiate, divided again, two or three-parted, the laſt three or four-flowered. Flowers whitiſh. Calyx ſix or eight-leaved, conical, ſmall. Corollets commonly four, ſeldom three. Stigmas reflex, cirrhoſe. Seeds conical-cordate, crowned with a feathered egret. This is remarkable for the very pleaſant odour of the whole plant, which continues many years even when dried.

2. This much reſembles the preceding, but the leaves are oblong, the flowers ſmaller; the calyxes conſtantly three-flowered, and the plant is almoſt void of ſcent. Native of Jamaica, much more common than the preceding in ſimilar ſituations[c].]

3. The third ſort riſes with an upright round ſtalk to the height of three feet, ſending out ſeveral branches towards the top, which come out regularly by pairs. The leaves are alſo in pairs, they are two inches and a half long, and about one-third of an inch broad, of a light green colour, and entire. The flowers ſtand upon long peduncles at the ends of the branches, ſome ſuſtaining one, ſome two, and others three or four flowers; they are white, and appear late in autumn. Native of Carolina, Virginia and Maryland.

[It has alſo been found in Japan by Thunberg.

Cultivated in the Cheliea garden before 1699.]

4. Stems annual, twiſting about any neighbouring ſupport to the height of five or ſix feet. At each joint two ſmall ſide-branches come out, terminated by cluſters of white flowers, ſo that the ſtalks ſeem covered with them moſt part of their length; but as theſe come out late in the ſeaſon, unleſs the ſummer prove warm, this plant does not flower well in England. Native of Virginia and Carolina.

[It is alſo ſuppoſed to be a native of the Eaſt-Indies, and to be the ſame with that which is figured by Burman *ind.* 176. *t.* 58. *f.* 2.—The Indian plant is ſmoother, and the teeth of the leaves more obſcure[d]. Cultivated in 1714[e].

5. This differs from the preceding in having the branches, petioles, nerves of the leaves underneath, and peduncles villoſe, the leaves leſs attenuated, with the lobes not divaricated, but parallel, the egret purpliſh, but not hoary. Native of the Eaſt-Indies.—There is another Eupatorium from Madagaſcar in every reſpect like this, except that it is entirely ſmooth.

6. Stem climbing: the branches have five acute angles, ſtanding out. Leaves petioled, two inches long, bluntiſh, paler underneath, very finely and thinly haired, ſometimes not toothed. Corymbs terminating the branches and branchlets: pedicels umbelled, filiform, rugged, angular. Calyx four-leaved; *leaflets* linear, equal, ſhorter than the egret, which is purpliſh. Native of Surinam.

7. Branches the thickneſs of a ſwan's quill, ſmooth, ſtriated; branchlets axillary, a hand in length, flower-bearing. Leaves petioled, three inches in length and breadth, ſmooth and nerved above, beneath ſlightly tomentoſe, with ſtellate hairs, viſible only with a magnifier, and having veins ſtanding out; the leaves on the branchlets are an inch long, and become gradually ſmaller towards the top. Corymbs from the extreme axils of the leaves on the branchlets, and from the end. Peduncles oppoſite, angular; the partial ones umbelled, in fives, ancipital, broader at top: pedicels in threes, three-flowered; flowers ſeſſile: at the baſe of the partial peduncles and flowers a pair of linear leaves. Calyx four-leaved; leaflets ſtriated, two more tender than the others. Seeds *four*, angular. Egret longer than the calyx, purpliſh. Found in the Caribbee iſlands by Martſelt, and in Surinam by Rolander[f].]

8. Stalks ſlender, twining, eight or ten feet high, ſending out ſmall oppoſite branches at moſt of the upper joints. Lower leaves heart-ſhaped, ending in acute points; upper almoſt triangular, ſmooth, and of a lucid green. The upper part of the ſtalks has long branching ſtalks of white flowers, which are ſmall and ſeſſile. It was ſent to Mr. Miller from Jamaica by Dr. Houſtoun.

[9. Leaves alternate, narrower at the baſe, with ſmall rounded ears bent in, green and ſmooth on the upper ſurface, tomentoſe and veined on the lower like Sage. The corymbs of flowers reſemble thoſe of the *Eupatoriums*[g]: the fructification, however, wants to be examined more critically[h]. Native of Ceylon.

10. Stems ſlender, round, ſmooth. Leaves in pairs, at two inches diſtance, ſeſſile, two inches long, mucronate, reſembling thoſe of Mint, ſlightly toothed on the edge. Flowers terminating, corymbed, in many little heads, white, ſlender. Native of Virginia; whence it was ſent to Bobart by the Rev. John Baniſter. Introduced in 1777, by Monſ. Thouin. It flowers in ſeptember and october.

11. Stem erect, ſtreaked, ſcarcely pubeſcent. Leaves oppoſite, ſubſeſſile, almoſt naked. Corymb terminating, compoſed of alternate, ſubdivided branchlets, ſaſtigiate and white. Down ſimple. Flowers like thoſe of *Calea oppoſitifolia*[i]. Found in Penſylvania by Bartram. Alſo in Japan by

[a] Browne. [b] Hort. kew. [c] Swartz. [d] Linn. ſyſt. [e] Hort. kew. from Philoſ. tranſ. [f] Vahl. [g] Linn. zeyl. [h] Linn. ſyſt. [i] Linn. mant.

Thunberg.

Thunberg, who describes the stem as round, villose, spotted with purple, and branched. The branches nearly opposite, decussated and patulous. The leaves ovate oblong, sharp, pubescent, an inch or more in length.

12. Stem somewhat angular, flexuose-erect, smooth, but little branched, a foot high or more. Leaves opposite, sharp, entire at the base, pale underneath, nerved, smooth, spreading, an inch and more in length. Flowers in a fastigiate and roundish panicle[a]. Native of China and Japan.

13. Stem round, streaked, erect, branched, two feet and upwards in height. Branches alternate, panicled, from erect-patulous, like the stem. Leaves opposite, petioled, the lower three-lobed, the upper undivided, ovate, sharp, unequally serrate, sometimes entire, paler underneath, nerved, scabrous, a finger's length, the upper ones gradually less. Petioles half an inch in length. Flowers on the branches and branchlets terminating, in ovate panicles, on very short peduncles.——Native of Japan[b].

14. This rises with upright stalks about a foot high: the joints are near each other, and at every joint is a pair of leaves, of a light green colour, and serrate. The flowers are produced in small loose panicles at the tops of the stalks; they are white, and have two small leaves immediately under them. The flowers appear at the end of june, but the seeds seldom ripen in England. Native of New-England and Virginia.

[This was cultivated in 1731, by Mr. Miller[c].

15. Stem very smooth, and very finely streaked. Leaves an inch and half or more in length, mucronate, acuminate at the base, veined, very smooth above, beneath appearing very slightly villose with a magnifier; lobes ovate, acute, oblique behind, having frequently one or two minute teeth. Petiole shorter than the leaf. Stipules two on each side, wedge-shaped, mucronate. Corymbs axillary and terminating, compound, peduncled; having two leaves of the same structure with those on the stem under the partial peduncles; which are in threes, trifid and many-flowered: pedicels capillary, with a bristle-shaped bractle towards the flower. Calyx simple, smooth, with four linear leaflets. Corollets four. Seeds the length of the calyx, with a purplish egret. Native of Brasil[d].]

16. This rises with a single upright green stalk, about four feet high. At each joint are four leaves in whorls: they are six inches long, and two inches broad in the middle, lessening to both ends, terminating in acute points, rough, serrate, and on short foot-stalks. Stem terminated by a close corymb of purple flowers, appearing in july, and continuing till september. Native of North America.

[Cultivated in 1768, by Mr. Miller[e]; and probably in the last century at Oxford[f].

17. Stem shrubby, branched, striated, pubescent. Leaves petioled, opposite; petioles also pubescent. Racemes axillary, opposite: flowers spiked in whorls, four in a whorl, white. Calyx four-leaved; leaflets lanceolate-ovate, convex. Corollets four. Stamens extremely minute. Style longer. Egret bristly, with the bristles very minutely serrate. The flowers smell like those of Cacalia suaveolens; the taste of the whole herb is bitter[g].

This is a climber, and stretches a great way among the neighbouring bushes. It is frequent about St. Thomas's in the East, and Manganeel, in Jamaica[h].

18. Stems straight, round, four or five feet high, purplish, striated: branchlets come out at a right angle almost over the whole stem. Leaves obscurely villose on both sides: leaflets subsessile, lanceolate, acute, sometimes gashed a little, the side ones smaller, frequently on the branches very small. Flowers in compound erect corymbs. Calyx five-leaved, five-flowered; leaflets oblong, obtuse, channelled, ciliate. Corollets purple, three times as long as the calyx. Egret sessile, white, hairy, with little prickles, apparent only to the magnifier. Flavour unpleasant and bitterish. It flowers in october[i].

19. Stem very finely striated, scarcely pubescent. Leaves petioled, alternate; the parts lanceolate, attenuated, serrate on the outside, smooth; the upper ones undivided, lanceolate, quite entire. Corymbs from the upper axils, and at the top, on long peduncles, compound: partial peduncles and pedicels subpubescent. Calyxes smooth, five-flowered: leaflets smooth, about ten, linear, the five outer ones very short. Native of the Caribbee islands[k].]

20. Stems upright, in a moist soil seven or eight feet high. Leaves oval, rough, lanceolate, a little serrate, in whorls of four, five or seven at each joint, three inches long, and two broad. The stems are terminated by a loose corymb of purple flowers, which appear in august, and continue till october, but are not succeeded by seeds in England.

[The leaves are shaped like those of the Sunflower, but are many times smaller. Stem slender, cylindric, rigid, hairy on the upper part. Flowers very small, as in the other species, but they have not the calyxes so long, nor are they so exactly disposed in umbels (corymbs), but rather like the common Red Valerian[l]. Gronovius found it in Virginia; Vernon brought it from Mariland; Miller says that it grows in Pensylvania; Krocker relates that it is found in Silesia, and that it is like our common European sort, except in having leaves in threes, and white flowers. Miller's can hardly be Linneus's plant.

21. Stems three or four, and even six feet high, hairy, reddish, branched. Leaflets three or five, lanceolate, sharply serrate on the sides, entire at the base and top, slightly hairy; the middle one much larger than the others. Scales of the calyx few, not more than ten, unequal, linear, red on the edge, a little hairy. Flowers in thick umbels or corymbs at the top of the stem or branches. Florets five, and sometimes six together, of a pale red or purple colour. Seeds black, streaked, smooth, little more than a line in length. Egret sessile, with simple rays, not three lines long: the rays, when viewed with a glass, are finely toothed[m], or shortly ciliate. The stem has a pleasant aromatic smell, when cut[n]. The flowers have a strong smell[o]. The whole plant has a very bitter taste: a handful of it vomits and purges smartly. An ounce of the root in decoction is a full dose; and is sometimes taken in the jaundice, dropsy, &c. but it is a rough medicine, and ought to be used with caution. Boerhaave gave an infusion of this plant to foment ulcers and putrid sores. Tournefort informs us, that the Turks cure the scurvy with it.—Of all cattle goats alone seem to eat it[p].

On the banks both of running and stagnant waters, frequently in most parts of Europe; flowering in july and august. In Johnson's edition of Gerarde it is named *Common Dutch Agrimony*.

β. Is the seedling plant, and has oval-lanceolate leaves; it sometimes flowers in that state, but not often: the second year it bears leaves in threes[q].

Professor John Martyn found this variety with simple leaves, but forgot the place. Dillenius met with it afterwards before you come to Lee in the road to Eltham[r]. Mr. Woodward has since observed it near Bungay in Suffolk.

22. Leaves four inches long, mucronate, with opposite nerves, with three remote teeth on each side. Petioles an inch long, dilated at the base. Corymbs terminating, superdecompound. Common peduncle pubescent: pedicels having minute scales scattered on them towards the base. Calyx seven-flowered; the outer scales ovate, shorter; the inner longer, linear. Egret purplish, twice as long as the calyx, almost simple. Supposed to be a native of South America[s].

[a] Thunberg. [b] Ibid. [c] Hort. kew. [d] Vahl. [e] Hort. kew. [f] Morison. [g] Swartz. [h] Browne. [i] Jacquin. [k] Vahl. [l] Ray. [m] Woodw. Mss. Withering. Lightfoot. [n] Ray. [o] Krocker. [p] Lightf. & With. [q] Woodw. Mss. [r] Tourn. par. edit. angl. [s] Vahl.

23. This very much reſembles an *Athanaſia* in its flowers and woody rigid ſtem. Thunberg found it at the Cape of Good Hope [a].

24. Stem cylindric, green, but purpliſh at the baſe of the petioles. Leaves in fours or fives, green on both ſides. Corymb terminating. Calyxes fleſh-coloured. Corollas whitiſh. Anthers purple. Styles very long [b]. It grows to the height of three feet or more, with a ſuffruticoſe, upright, ſtriated ſtem, but little branched. The leaves are ſubſeſſile, and of a very dark green. The corymb of flowers is faſtigiate. The calyx has about eight flowers [c]. The receptacle is narrow, convex, ſcrobiculate, ſmooth. The ſeeds are ſmall, four-cornered-columnar, acuminate at the baſe, with the ſtreaks and angles rugged with dots, and whitiſh, the interſtices ſmooth and livid. Egret capillary, very minutely toothletted [d]. Native of North America and Cochinchina.

Cultivated in 1731, by Mr. Miller [e].

25. The whole plant is ſmooth. Leaves petioled, oppoſite, ſharp at both ends. Panicle terminating, large, a foot long: the laſt pedicels capillary: at all the ramifications oppoſite, narrow leaves, becoming gradually ſmaller. Calycine leaflets lanceolate, the outer ones ſhorter. Corollets eight. Egret white, the length of the calyx. Native of South America [f].

26, 27. Natives of Jamaica [g].]

28. Stem annual, about two feet and a half high, purple, with many dark ſpots upon it. Leaves rough, placed by threes towards the bottom of the ſtalk, but near the top by pairs at each joint. Flowers purple, terminating in a ſort of corymb, appearing in july and auguſt, and in warm ſeaſons ripening the ſeeds in autumn. [Egret ſimple or capillary [h]. Native of North America; and cultivated here in 1656, by Mr. John Tradeſcant, jun. [i]

29. Stem woody: branches ſtriated, tomentoſe-hoary, becoming bald with age. Leaves alternate, two inches long or leſs, remote, acute, minutely toothletted, except the uppermoſt, which are quite entire, the upper ſurface ſmooth, five-nerved or thereabouts, ſomewhat dotted, hoary, ſimply veined. Petioles tomentoſe, half an inch in length, with a half-ovate, tomentoſe earlet at the baſe on each ſide; the laſt floral leaves having only a rudiment of theſe. Spike compound, flexuoſe, axillary and terminating. Spikelets alternate. Flowers uſually in pairs, diſtant; in the axils of the branches of the ſpike ſingle. Calyx ſmooth, with eight linear leaflets, of a brown ferruginous colour; and at the baſe a few minute tomentoſe ſcales. Corollets ſeven. Style longer by half than the corollet. Egret a little longer than the calyx, white, when magnified appearing ſerrate. Native of Braſil [k].

30. Native of Guiana, Jamaica, &c. Annual [l].

31. Branches ſoftly villoſe. Leaves petioled, an inch and half in length or ſmaller, a little attenuated, either quite entire or ſlightly ſerrate, bluntiſh, three-nerved, the younger ones villoſe on both ſides, the lower ones ſmooth on the upper ſurface, and ſomewhat rugged. Corymbs terminating, decompound. Peduncles and pedicels villoſe-tomentoſe. At the ramifications ſhort, briſtle-ſhaped leaves. Calycine leaflets linear, pubeſcent. Corollets ſmall, as far as ſixteen. Seeds the length of the calyx, with a dirty-coloured egret, longer than the calyx [m]. Native of Jamaica and Domingo [n].

32, 33. Natives of Jamaica [o].

34. This is a branching ſhrub; the branches having an aſh-coloured bark: branchlets oppoſite, brachiate, ſpreading, hoary and very ſoft, as are alſo the tops of the branches. Leaves petioled, oppoſite; on the branches an inch long, very blunt, ſub-lobed, with one or two large notches, greener above, hoary and ſofter beneath; on the branchlets half an inch in length, gradually ſmaller towards the top; the lower ones obſcurely lobed, the upper ones entire, hoary and ſoft on both ſides; all having nerves which are more conſpicuous underneath, often obſcurely veined, but more generally veinleſs. Corymbs from the ends of the branches and branchlets, few-flowered. Calyx cylindrical, ſubvilloſe: leaflets linear, obtuſe, with pale ſtreaks, the outer ones ſhorter. Florets ten. Seed black, when magnified appearing angular, with minute villoſe hairs ſcattered over it. Obſerved in the iſland of Santa Cruz by Pflug and Weſt [p].

35. The ſtem ſeems to be underſhrubby; it is upright, branched, roundiſh, ſtreaked, villoſe-ſcabrous, leafy, many-flowered. Branchlets oppoſite, angular, bearing flowers at the end. Leaves oppoſite, on ſhort petioles, from erect ſpreading, acuminate, ſubſerrate, very ſeldom entire, viſcid, uſually three-nerved, rough, with hairs on the upper ſurface, and very ſcabrous on the lower. No ſtipules. Panicles terminating, upright, rough with hairs, many-flowered, contracted. Peduncles oppoſite. Pedicels moſtly alternate. Bractes lanceolate, rough with hairs. Flowers upright. Calyx cylindric, ſmooth; ſcales oblong, obtuſe, three-nerved, ſomewhat callous at the tip, the outer ones ſhorter and broader. Florets ſeven or eight, ſcarcely longer than the calyx, five-fided. Seeds black; with a down ſcarcely the length of the corolla, ſerrate, hardly feathered, ſpreading.—Gathered by Mutis in New Granada [q].]

36. Stems annual, from two to three feet high, hairy. Leaves at each joint rough, from three to four inches long, and about an inch broad at their baſe, gradually leſſening to a very acute point, dark green, and covered with ſhort hairs. The upper part of the ſtalk divides into many ſlender peduncles, each ſuſtaining a cloſe cluſter of white flowers, coming out in july. In warm ſeaſons the ſeeds will ſometimes ripen in England. Native of North America.

[Cultivated in the botanic garden in Chelſea in 1699 [r].]

37. This has a creeping root, which ſpreads and multiplies very faſt. The ſtalks riſe about two feet high. The flowers are produced at the top of the ſtalks in a ſort of corymb, and are of a fine blue colour.

[Dr. Dale ſent the ſeeds from Carolina to Mr. Miller; and it was alſo cultivated in 1732 in the Eltham garden. Petiver and Plukenet received it from Maryland.

38. Stem round, four feet high, ſtrict, brachiate, having the appearance of *Scutellaria*. Leaves ſomewhat wrinkled. Racemes terminating. Flowers twice the length of the calyx, ſnow-white, containing from eighteen to twenty-eight florets, the ſtyles ſcarcely longer than the floret: in this circumſtance it differs from the other ſpecies, and in having the calyx not imbricate, but the leaflets almoſt equal: thus it approaches to *Ageratum*; but it has a true down to the ſeeds.—Native of Virginia [s].—Cultivated in 1758, by Mr. Miller [t].

39. Stem the thickneſs of a Swan's quill, ſtriated, pubeſcent. Branches axillary, from erect-ſpreading. Leaves oppoſite, large, ſmooth above, except the veins, pubeſcent and paler underneath, veined, bluntly ſerrate, ſharp at the end; the uppermoſt frequently alternate. Petioles from two to three inches in length. Corymbs terminating and axillary, peduncled, decompound, cloſe. Calyx looſely imbricate; the leaflets lanceolate, pale green, very finely ſtreaked. Native of the Caribbee iſlands [u].]

40. Stems annual, five or ſix feet high, towards the top putting out ſide branches. At the ends of the ſhoots the flowers are produced in large tufts, and are of a pure white; they appear in october.

[Calycine

[Calycine ſcales linear-acuminate. Receptacle convex, ſcrobiculate, ſmooth. Seeds oblong, four-cornered, ſtriated, ſmooth, pale, remarkably attenuated at the baſe. Egret capillary[b]. Native of North America.

Introduced before 1640, by John Tradeſcant, ſen[c].

41. Branches ſtriated, pubeſcent. Leaves acuminate, ſcarcely pubeſcent underneath, an inch and half in length. Corymb terminating, almoſt ſimple, few-flowered: partial peduncles three-flowered; pedicels one-flowered. Calyx as in E. ordoratum, but larger, cylindric, a little broader at top: leaflets linear, pale, with rounded brown tips. Suppoſed to be a native of South America[d].

42. Stem a fathom in height, ſhrubby, branched, even. Leaves oppoſite, petioled, three-nerved, dotted. Flowers terminating, ſubcorymbed, white. Seeds linear, ſlightly compreſſed, with a capillary egret[e].

This weakly ſhrubby plant is generally obſerved to grow among other buſhes, where it frequently caſts its long, ſlender, flexile, oppoſite branches to a moderate diſtance. The flowers are ſometimes impregnated with a ſmell perfectly like that of the European Meadow-ſweet. It is very frequent in the lower hills of Jamaica[f].—Introduced in 1780, by William Wright, M.D. It flowers in auguſt and ſeptember[g].

43. Stem round, ſmooth, very finely ſtreaked; branches ſpreading, flower-bearing. Leaves oppoſite, attenuated at the baſe, ſubſeſſile, from two to three inches in length, veined. Panicle terminating, ſubtrichotomous: partial peduncles ſcarcely pubeſcent: the laſt pedicels an inch long, filiform: with a minute leaf at the baſe of each. Calyx many-leaved; leaflets linear, nearly equal, acute, villoſe and purpliſh at the tip, the utmoſt ſhorter. Florets more than twenty, purple at top. Stigmas half as long again as the corollets. Egret whitiſh, the length of the calyx. Sent from the iſland of Santa Cruz by Pflug[h].

44. Stem ſubherbaceous, two feet high, erect, ſtrict, branched, hiſpid: branches ſimple, elongated. Leaves petioled, oppoſite, ſomewhat rugged; lower ones lanceolate, longer, ſpreading. Peduncles terminating, and in the axils of the upper leaves, oppoſite, filiform, moſtly trichotomous, but the laſt one-flowered. Flowers ſmall, blue. Common in Jamaica[i].

45. This at firſt ſight is very much like a nettle, but the leaves are three-nerved at the baſe, as in *Scrophularia nodoſa*, *Arctium Lappa*, &c.—Stem upright, branched, round, ſtreaked, hairy, leafy. Leaves oppoſite, ſpreading very much, bluntiſh, deeply and irregularly ſerrate, veined, hiſpid, with hairs on both ſides, paler underneath. Petioles ſcarcely the length of the leaves, angular, equal. No ſtipules. Panicle like a cyme, upright, hairy. Pedicels alternate or crowded. Bractes linear, few. Flowers upright, pale purple. Calyx ſubcylindric, patulous, pubeſcent; ſcales keeled, three-nerved, attenuated at the edge; the outer ones ſmaller. Floſcules little longer than the calyx. Seeds black. Down ſhorter than the corolla; viewed with a glaſs appearing to be minutely ſerrate.

46. Stem upright, roundiſh, covered with a ſoft, thick, white down. Leaves oppoſite, on ſhort petioles, ſpreading, blunt, flat, marked with one nerve, but with numerous little veins, divaricate, alternate; the upper ſurface green, with a ſoft down, the lower white, with a cloſe wool, as are alſo the ſtem and petioles. No ſtipules. Panicles upright, ſomewhat like corymbs, conglomerate. Peduncles oppoſite, variouſly divided, woolly. Bractes none, except a pair of leaves ſmaller than the reſt, at the baſe of each panicle. Flowers purple. Calyx cylindric, woolly at the baſe: ſcales ſharp, with a green line along them, membranaceous and ciliate about the edge; the inner ones ſomewhat tongue-ſhaped, the outer lanceolate and ſmaller. Floſcules very numerous, the length of the calyx, a little ſwelling, five-fided; ſegments from erect ſpreading, ſharpiſh, quite entire, ſcarcely pubeſcent. Anthers included. Style ſcarcely half-cleft. Down ſhorter than the corolla, yellowiſh, ſcrabrous.

47. Stem underſhrubby, woody, aſcending, a little branched, leafy, round, ſubhirſute. Leaves oppoſite, ſpreading, petioled, ſmall, blunt, with the edge rolled back, having four (ſeldom three or five) notches on each ſide, and one at the end; ſtiffiſh, thickiſh; green and ſmooth on the upper ſurface, woolly, white, and veined like a net on the under. Petioles the length of the leaves, hairy. No ſtipules. Panicle on a long peduncle, reſembling a corymb. Pedicels variouſly divided, rough-haired. Bractes two at the firſt ramification of the panicle, uſually lanceolate, but ſometimes of the ſame form with the leaves. Flowers purple, ſewer than in the foregoing. Calyx ſubcylindric, ſcarcely pubeſcent at the baſe; all the ſcales lanceolate, ſharp, nerved attenuated and ciliate at the edge; the outer ones ſmaller and thicker. Floſcules ſcarcely the length of the calyx, ſwelling at top, not angular; ſegments from erect ſpreading, bluntiſh, entire, cloſely pubeſcent on the outſide. Anthers included. Style ſcarcely half-cleft. Seeds brown. Egret almoſt the length of the corolla, hardly rugged when viewed through a glaſs. The flowers reſemble thoſe of the preceding in ſtructure, but differ in ſeveral characters. Theſe three ſpecies were found in New Granada by Mutis[k].

48. Stems a fathom in height, round, ſubtomentoſe, with oppoſite branches. Leaves oppoſite, deep green above, beneath paler, ſomewhat tomentoſe. Flowers in racemes, on axillary three-flowered peduncles. Calyx cylindric, with many lanceolate-acute, ſtriated leaflets, the outer ones reflex at the tip, and containing about twenty-four florets. Corolla twice as long as the calyx: florets greeniſh-yellow, with ſhort, ovate-acute, patulous ſegments. Seeds ſmall, oblong, ſtriated, with very ſmall hairs. Egret ſeſſile, obſcurely feathered, ſhorter than the corolla. Native of Mexico. Flowering in the month of march in the royal garden near Madrid, before 1791[l].

49. Stem ſuffruticoſe, three feet high, erect, hiſpid. Leaves toothletted. Flowers purpliſh, in terminating panicles. Receptacle concave. Native of the iſland of Mozambique on the coaſt of Africa[m]. This belongs to the third ſection with eight-flowered calyxes.]

Beſides theſe, Miller has five ſorts, which were ſent him from La Vera Cruz by Dr. Houſtoun.

1. Eupatorium fruticoſum, n. 6. with oblong-cordate leaves, flowers in panicles, ſtem ſhrubby climbing.—It riſes to the height of ten or twelve feet: the leaves are oppoſite, about three inches long, and an inch and half broad, of a lucid green: the panicles are long and branching, and proceed from the ſide of the ſtalks: the flowers are white.

2. Eupatorium betonicifolium, n. 9. with oblong blunt crenate ſmooth leaves, and ſimple calyxes.—It riſes with an upright ſtem near two feet high, having towards the bottom leaves of a thick ſubſtance: from the upper part, which is naked, the flowers come out in a thick panicle; their colour is blue, and they come out late in autumn. The root is biennial.

3. Eupatorium morifolium, n. 10. with heart-ſhaped ſerrate leaves, and an upright tree-like ſtem. This riſes twelve or fourteen feet high, ſending out many channelled branches, covered with a brown bark. Leaves as large as thoſe of the mulberry-tree, of a light-green colour, oppoſite, on petioles near two inches long. Branches terminated by four or five pairs of peduncles, which come out oppoſite from the joints; there is alſo an odd one at the end; theſe ſuſtain branching panicles of white flowers forming a long, looſe, pyramidal thyrſe, without any leaves intermixed, and making a fine appearance.

[a] Gærtner. [c] Hort. kew. [d] Vahl. [e] Swartz.
[f] Browne. [g] Hort. kew. [h] Vahl. [i] Swartz.
[k] Smith. [l] Cavanilles. [m] Loureiro.

4. Eupa-

4. Eupatorium punctatum, n. 11. with ovate petioled entire leaves, ſtem ſhrubby branching, calyxes ſimple.—Stems near five feet high, dividing into many ſlender branches, the joints of which are three or four inches aſunder; at each of theſe is a pair of leaves, about three quarters of an inch long, and half an inch broad, having ſeveral black ſpots on their ſurface, and upon long ſlender foot-ſtalks: the branches are horizontal, terminated by ſmall bunches of white flowers. The calyxes are compoſed of ſeven narrow-lanceolate leaflets, divided to the bottom.

5. Eupatorium paniculatum, n. 15. with heart-ſhaped wrinkled crenate leaves, and a panicled ſtem.—This riſes with an upright branching ſtem three feet high, ſending out two ſide branches from every joint, almoſt the whole length; theſe are terminated by looſe ſpikes of red flowers, as is alſo the principal ſtem. The leaves are rough, ſeſſile, of a light green, and a little hoary.

Eupatorium conyzoides, n. 14. may probably be the ſame with Kuhnia conyzoides of Linneus.

PROPAGATION AND CULTURE.

The North American ſorts (n. 3, 4, 10, 11, 14, 16, 20, 23, 28, 36, 37, 38, 40.) being hardy plants the ſeeds may be ſown in the full ground, but there muſt be care taken in the ſowing to keep the ſorts ſeparate; for as the ſeeds of theſe plants have a light down adhering to them, they are eaſily diſplaced by the leaſt wind; ſo that the beſt way will be to ſow them in drills, but theſe ſhould be but ſhallow, for if the ſeeds are buried too deep they will not grow. The bed in which theſe are ſown ſhould not be too much expoſed to the ſun, but rather have an eaſt aſpect, where the morning ſun only reaches it; but where it is more expoſed, it ſhould be ſhaded with mats in the heat of the day, and the ground ſhould be kept pretty moiſt; for as theſe plants generally grow in moiſt ſhady ſituations in their native countries, they will ſucceed better when they have a ſoil and ſituation ſomewhat like that; though as we want their heat in ſummer, the plants will thrive here when expoſed to the ſun, provided they have a moiſt ſoil, or are ſupplied with water in dry weather.

When the young plants come up, they muſt be kept clean from weeds; and where they are too cloſe, ſome of them ſhould be drawn out, to give room for the others to grow; and if theſe are wanted, they may be planted in another bed, where, if they are ſhaded and watered, they will ſoon take root; after which they will require no farther care but to keep them clean from weeds till the following autumn, when they may be tranſplanted to the places where they are to remain. As the roots of theſe plants ſpread out to a conſiderable diſtance, they ſhould not be allowed leſs than three feet from any other plants, and ſome of the largeſt growing ſhould be allowed four feet. If the ſoil in which they are planted is a ſoft gentle loam, they will thrive much better, and flower ſtronger than in light dry ground; in which, if they are not duly watered in dry ſummers, their leaves will ſhrink, and their ſtalks will not grow to half their uſual height.

All theſe ſorts have perennial roots, by which they may be propagated; and as ſome of them do not perfect their ſeeds in England, that is the only way of increaſing the plants here; ſome of the ſorts have creeping roots, ſending out offſets in great plenty, ſo theſe are eaſily propagated; and the others may be taken up, or the heads taken off from them every other year, in doing of which there ſhould be care taken not to cut or injure the old plants too much, which would cauſe them to flower weak the following year. The beſt time to remove theſe plants is in autumn, as ſoon as they have done growing, that they may get freſh roots before the froſt comes on; but if that ſhould happen ſoon after their removal, if the ſurface of the ground is covered with tan, or dried leaves, to keep out the froſt, it will effectually ſecure them; and if this is done to the old plants in very ſevere winters, it will always preſerve them; however, it may not be amiſs to practiſe this on the young ſeedling plants, which have not ſo good roots, nor are ſo well eſtabliſhed in the ground; the future culture will be only to dig the ground about them every ſpring, and keep them clean.

The fourth ſort however is ſometimes killed in very ſevere weather, if not covered; when the ſtalks therefore decay in autumn, the ground ſhould be covered with ſome old tanner's bark. It multiplies very faſt by its creeping roots, which may be parted every other year.

The European ſort, (n. 21.) is ſeldom admitted into gardens, becauſe it is very common by water ſides; and wherever it is ſuffered to ſeed, the ground will be well ſtored with the plants to a great diſtance.

Thoſe which are natives of the Weſt Indies, and other hot countries (n. 1, 2, 5, 6, 7, 8, 9, 15, 17, 18, 19, 22, 25, 26, 27, 29, 30, 31, 32, 33, 34, 35, 39, 41, 42, 43, 44, 45, 46, 47, 48, 49.) being tender ſhould be planted in pots, and kept conſtantly plunged in the tan-bed in the ſtove, where they will thrive and flower. Theſe may be propagated by cutting off ſome of their young ſhoots about the middle of June, when they have ſtrength, planting them in pots filled with light earth, and plunging them into a moderate hot-bed, where, if they are ſhaded from the ſun, and gently watered as they may require it, they will put out roots in ſix weeks, and may then be tranſplanted into ſeparate pots, and treated as the old plants.

When the ſeeds of theſe tender ſorts can be had from their native countries, the plants raiſed that way are much preferable to thoſe which are obtained by any other method, and will flower much ſtronger, but as theſe ſeeds ſeldom grow the firſt year, few perſons have patience enough to wait for the plants coming up. When any of theſe ſeeds are brought over, they ſhould be ſown as ſoon as they arrive in pots, that they may be removed at any time; the pots ſhould be plunged into a moderate hot-bed, and the earth kept tolerably moiſt; the glaſſes ſhould alſo be ſhaded in the heat of the day, to prevent the earth from drying; in this hot-bed the pots may remain till autumn, when, if the plants are not up, they ſhould be plunged between the plants in the bark-ſtove, and in the ſpring removed to a gentle hot-bed, which will bring up the plants ſoon after. When theſe are fit to remove they ſhould be planted in ſeparate ſmall pots, and plunged into the hot-bed again, ſhading them from the ſun till they have taken new root; then they ſhould have a large ſhare of free air admitted to them in warm weather, and frequently refreſhed with water.

In the winter theſe plants ſhould be more ſparingly watered, eſpecially thoſe ſorts whoſe ſtalks decay; and in the ſummer they ſhould have a large ſhare of free air admitted to them, with which management they will thrive and flower.

Claſſ. 11. 3. Dodecandria Trigynia.

Nat. order of *Tricoccæ*.—*Euphorbiæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, inflated, ſomewhat coloured, four-toothed at the mouth, (in ſome few five-toothed,) permanent.

COR. *Petals* four, (in ſome few five,) turbinate, gibbous, thick, truncate, unequal in ſituation, alternate with the teeth of the calyx, with their claws placed on the margin of the calyx, permanent.

STAM.

STAM. *Filaments* several (twelve or more) filiform, jointed, inserted into the receptacle, longer than the corolla, breaking forth at different times. *Anthers* twin, roundish.

PIST. *Germ* roundish, three-sided, pedicelled. *Styles* three, two-cleft. *Stigmas* obtuse.

PER. *Capsule* roundish, tricoccous, three-celled, starting open elastically.

SEEDS solitary, roundish.

OBS. Euphorbium Isn. *has a shrubby cornered or fleshy stem, mostly leafless; prickly in some, and unarmed in others; the petals in some three-cleft.*

Tithymalus T. *has a leafy stem, most often herbaceous, always cylindric and without prickles.*

Tithymaloides T. *has the calyx bulging towards the lower side, shoe-shaped.—In some species the male flowers are first.*

The petals are generally four, in some five; often on the same plant, the flowers differing in sex. Those (petals) are in most glandulous, in others mooned or toothed, in a few thin like a membrane. Commonly placed in a manner beyond the calyx.

The capsule is either smooth or hairy, or warty.

ESSENTIAL CHARACTER.

Cor. four or five-petalled, placed on the calyx. *Cal.* one-leafed, bellying. *Capf.* tricoccous.

SPECIES.

* *Shrubby, prickly.*

Burm. afr. 18. *t.* 9. *f.* 1.
Imbricate, tubercles furnifhed with a linear leaf, flowers fubpeduncled, petals palmate.

12. Euphorbia Clava. *Club Spurge.*
Jacqu. ic. collect. 1. 104. *Ait. hort. kew.* 2. 136. *Burm. afr.* 12. *t.* 6. *f.* 1. *Comm. præl.* 58. *t.* 8.
Imbricate, tubercles, furnifhed with a lanceolate leaf, flowers peduncled, petals quite entire.]

13. Euphorbia anacantha. *Scaly Spurge.*
Ait. hort. kew. 2. 136. *Ifnard. act. par.* 1720. *p.* 387. *n.* 12. & 392. *t.* 11. *Burm. afr.* 16. *t.* 7. *f.* 2.
E. procumbens. *Mill. dict. n.* 12?
Imbricate, tubercles furnifhed with a roundifh leaflet, flowers terminating folitary feffile, petals palmate.

14. Euphorbia mauritanica. *Barbary Spurge.*
Lin. fpec. 649. *Reich.* 2. 438. *hort. cliff.* 197. *upf.* 140. *amæn.* 3. 111. *Gron. orient.* 160. *Dill. elth.* 384. *t.* 289. *f.* 373.
Half naked fhrubby filiform flaccid, leaves alternate.

[15. Euphorbia pitcatoria. *Smooth Spearleaved Spurge.*
Ait. hort. kew. 2. 137.
Shrubby ftrict, umbels five cleft terminating, involucels * *oblong, leaves linear even.*

16. Euphorbia glabrata. *Smooth Spurge.*
Swartz prodr. 76. *Vahl fymb.* 2. 53. *Sloan. jam.* 2. 198. (Peplis.)
Unarmed fhrubby branched, leaves oppofite ovate acute fmooth quite entire.

17. Euphorbia linifolia. *Flax-leaved Spurge.*
Vahl fymb. 2. 53.
Stem fuffruticofe, leaves oppofite and alternate linear-lanceolate.

18. Euphorbia cuneata.
Vahl fymb. 2. 53.
Shrubby, leaves obovate, peduncles lateral three-flowered.

19. Euphorbia balfamifera. *Balfam Spurge.*
Ait. hort. kew. 2. 137.
Shrubby ftrict, head terminating, leaves lanceolate, even, glaucous.]

20. Euphorbia Tirucalli. *Indian Tree-Spurge.*
Lin. fpec. 649. *Reich.* 2 438. *hort. cliff.* 197. *upf.* 139. *fl. zeyl.* 196. *amæn.* 3. 111. *Lour. cochinch.* 299. *Comm. hort.* 1. 27. *t.* 14. *Pluk. phyt. t.* 319. *f.* 6. (Tithymalus). *Rumph. amb.* 7. 62. *t.* 29 *Rheed. mal.* 8. *t.* 44.
Half naked fhrubby filiform, erect, branches patulous crowded in an orderly manner.

21. Euphorbia Tithymaloides.
Lin. fpec. 649. *fyft.* 449. *Reich.* 2. 438. *hort. cliff.* 198. *amæn.* 3. 111. *Jacqu. amer.* 149. *t.* 92. *pict.* 74. *t.* 138.
α. E. myrtifolia. *Myrtle-leaved Spurge.*
Tithymalus myrtifolius. *Mill. dict. n.* 1. *Herm. part.* 1. 234. *Comm. hort.* 1. 31. *t.* 16. *Pluk. alm. t.* 230. *f.* 2.
β. E. padifolia. *Laurel-leaved Spurge.*
Tithymalus laurocerafolius. *Mill. dict. n.* 2.
Tithymaloides laurocerafi folio non ferrato. *Dill. elth.* 383. *t.* 288. *f.* 372.
Shrubby, leaves in a double row alternate ovate.

22. Euphorbia heterophylla. *Various-leaved Spurge.*
Lin. ſpec 649. *Reich.* 2. 439. *amæn.* 3. 112. *Retz. obſ.* 6. 30. *n.* 48. *Plum. ic.* 250. *t.* 251. *f.* 3. *Pluk. alm. t.* 12. *f.* 6. *Mor. hiſt.* 3. 336. 16. (Tithymalus).
Leaves ſerrate petioled differm ovate panduriform: (*dichotomous with a biſid umbel.*)

23. Euphorbia cotinifolia. *Venice-Sumach-leaved Sp.*
Lin. ſpec. 650. *ſyſt.* 449. *Reich.* 2. 439. *amæn.* 3. 112. *hort. cliff.* 198. *Pluk. alm. t.* 230. *f.* 3. *Seb. theſ.* 1. 75. *t.* 46. *f.* 4. *Comm. hort.* 1. 29. *t.* 15. (Tithymalus).
Leaves oppoſite ſubcordate petioled emarginate quite entire, ſtem ſhrubby.

24. Euphorbia ocymoidea. *Baſil-leaved Spurge.*
Lin. ſpec. 650. *Reich.* 2. 439. *amæn.* 3. 112.
Herbaceous branching, leaves ſubcordate quite entire ſhorter than the petiole, flowers ſolitary.

[25. Euphorbia lævigata.
Vahl ſymb. 2. 54.
Shrubby branched, leaves oppoſite oblong obtuſe ſmooth quite entire.

3. *Dichotomous.*
(*With a biſid umbel, or vne.*)

26. Euphorbia origanoides. *Marjoram Spurge.*
Lin. ſpec. 650. *Reich.* 2. 440. *amæn.* 2. 114.
Leaves ſerrulate ovate obtuſe three-nerved, panicle terminating, ſtems ſimple.

27. Euphorbia Atoto.
Forſt. fl. auſtral. n. 207.
Dichotomous, leaves ovate quite entire, umbel terminating.]

28. Euphorbia hypericifolia. *St. John's-wort-leaved Spurge.*
Lin. ſpec. 650. *Reich.* 2. 440. *amæn.* 3. 113. *hort. cliff.* 198. *upſ.* 143. *Swartz obſ.* 194. *Brown jam.* 235. 2. *Sloan. jam.* 1. 197. 14. *t.* 126. *Comm. prael. t.* 60. (Tithymalus).
Leaves ſerrate oval-oblong ſmooth, corymbs terminating, branches divaricate.

[29. Euphorbia mellifera. *Honey-bearing Spurge.*
Ait. hort. kew. 3. 493.
Leaves ſcattered lanceolate acute even, peduncles dichotomous, capſules muricated.

30. Euphorbia proſtrata. *Trailing red Spurge.*
Ait. hort. kew. 2. 139.
Leaves oval obſcurely ſerrate, peduncles axillary with about three flowers, ſtems diffuſed ſmooth.

31. Euphorbia maculata. *Spotted Spurge.*
Lin. ſpec. 652. *ſyſt.* 450. *Reich.* 2. 440. *Jacqu. hort.* 2. 87. *t.* 186. *Pluk. phyt. t.* 65. *f.* 8. (Tithymalus). *Sloan. jam.* 1. 198. (Chamæſyce).
Leaves ſerrate oblong hairy, flowers axillary ſolitary, branches patulous.

32. Euphorbia hirta. *Creeping hairy Spurge.*
Lin. ſpec. 651. *Reich.* 2. 441. *amæn.* 3. 114. *fl. zeyl. n.* 197. *Swartz obſ.* 195. *Brown. jam.* 234. *Burm. zeyl.* 223. *t.* 104. (Tithymalus). *Rumph. amb.* 6. 54. *t.* 23. *f.* 2. (Eſula).
Leaves ſerrulate ovate acuminate, peduncles in axillary heads, ſtems hairy.

33. Euphorbia pilulifera.
Lin. ſpec. 651. *Reich.* 2. 441. *amæn.* 3. 115. *Burm. zeyl.* 224. *t.* 105. *f.* 1. *Pet. gaz. t.* 80. *f.* 14. (Tithymalus).
Leaves ſerrate oval-oblong, peduncles in two axillary heads, ſtem upright.

34. Euphorbia hyſſopifolia. *Hyſſop-leaved Spurge.*
Lin. ſpec. 651. *Reich.* 2. 441. *Brown. jam.* 235. 4.
Leaves ſubcrenate linear, flowers faſcicled terminating, ſtem upright.

35. Euphorbia thymifolia. *Thyme-leaved Spurge.*
Lin. ſpec. 652. *Reich.* 2. 441. *amæn.* 3. 115. *fl. zeyl. n.* 198 *Pluk. alm. t.* 113. *f.* 2. *Burm. zeyl.* 225. *t.* 105. *f.* 3. (Tithymalus).
Leaves ſerrate oval-oblong, heads axillary glomerate ſubſeſſile, ſtems procumbent.

36. Euphorbia parviflora.
Lin. ſpec. 652. *ſyſt.* 450. *Reich.* 2. 442. *Burm. zeyl.* 224. *t.* 105. *f.* 2.
Leaves ſerrate oblong ſmooth, flowers ſolitary, ſtem ereciſſo alternately branched.

37. Euphorbia canefcens.
Lin. ſpec. 652. *Reich.* 2. 442. *Cavan. hiſp.* 46. *n.* 69. *t.* 63.
Leaves entire roundiſh hairy, flowers ſolitary axillary, ſtems procumbent.

38. Euphorbia Chamæſyce. *Crenated Annual Spurge.*
Lin. ſpec. 652. *Reich.* 2. 442. *mant.* 393. *amæn.* 3. 115. *hort. cliff.* 198. *Gmel. ſib.* 2. 237. *Gron. orient.* 160. *Brown. jam.* 236. 8. *Swartz obſ.* 196. *Villars dauph.* 3. 821.
Chamæſyce. *Bauh. pin.* 293. *Cluſ. hiſt.* 2. 188.
Leaves crenulate roundiſh ſmooth, flowers ſolitary axillary, ſtems procumbent.

39. Euphorbia rubra.
Cavan. hiſp. 21. *n.* 34. *t.* 34. *f.* 1.
Leaves wedge-ſhaped emarginate imbricate, umbels biſid, corollas five-petalled.

40. Euphorbia granulata.
Vahl ſymb. 2. 54. *Forſk. ægypt.* 94.
Dichotomous, leaves oppoſite oblong quite entire, flowers ſolitary, axillary, ſtems procumbent.

41. Euphorbia Peplis. *Purple Spurge.*
Lin. ſpec. 652. *Reich.* 2. 442. *amæn.* 3. 115. *Gron. orient.* 163. *Huſſ. angl.* 207. *With.* 494. *Smith brit.* 513. *Krock. ſileſ. n.* 722. *Vahl ſymb.* 2. 54. *Forſk. ægypt.* 93. *Villars dauph.* 3. 822.
Tithymalus Peplis. *Scop. carn. n.* 583.
T. maritimus ſupinus annuus, Peplis dictus. *Raii ſyn.* 313.
Peplis. *Cluſ. hiſt.* 2. 187. *Camer. epit.* 970. *Matth.* 1260. *Bauh. hiſt.* 3. 668. *Ger.* 406. 16. *emac.* 503. 20. *Park. theat.* 194. 7. *Raii hiſt.* 869.—maritima fol. obtuſo. *Bauh. pin.* 293. *Mor. hiſt.* 3. 340. *ſ.* 10. *t.* 2. *f.* 18. *Petiv. brit. t.* 53. *f.* 12.
Pephon. *Dalech. hiſt.* 1659.
Leaves quite entire ſemicordate, flowers ſolitary axillary, ſtems procumbent.

42. Euphorbia polygonifolia. *Knot graſs-leaved Sp.*
Lin. ſpec. 653. *Reich.* 2. 443. *amæn.* 3. 116. *Gron. virg.* 58. *Raii ſuppl.* 431. *n.* 51.
Leaves oppoſite quite entire lanceolate obtuſe, flowers ſolitary axillary, ſtems procumbent.

43. Euphorbia graminea.
Lin. ſyſt. 450. *Reich.* 2. 443. *mant.* 74. *Jacqu. amer.* 151. *pict.* 74. *t.* 139. *obſ.* 1. 5. *t.* 31. *Brown. jam.* 253. 3. *Swartz obſ.* 196?
Leaves lanceolate elliptic petioled quite entire, ſtem upright, peduncles dichotomous.

44. Euphorbia Ipecacuanhæ.
Lin. ſpec. 653. *Reich.* 2. 443. *amæn.* 3. 116. *Gron. virg.* 58. (Tithymalus).
Leaves quite entire lanceolate, peduncles axillary one-flowered equalling the leaves, ſtem upright.

45. Euphorbia portulacoides. *Purſlain-leaved Spurge.*
Lin. ſpec. 653. *Reich.* 2. 443. *amæn.* 3. 117.
Leaves quite entire oval retuſe, peduncles axillary, one-flowered, equalling the leaves, ſtem upright.

46. Euphorbia myrtifolia. *Myrtle-leaved Spurge.*
Lin. ſpec. 653. *Reich.* 2. 443. *Swartz obſ.* 197.
Leaves quite entire, roundiſh emarginate hoary underneath, flowers ſolitary, ſtem upright.

47. Euphorbia imbricata.
Vahl. ſymb. 2. 54.
Umbel dichotomous biſid, involucels roundiſh mucronate leaves obovate imbricate ſerrulate, ſtem fruticoſe.

4. *Umbel trifid.*

48. Euphorbia Peplus. *Petty Spurge.*
Lin. ſpec. 653. *Reich.* 2. 444. *amæn.* 3. 117. *hort. cliff.* 199. *fl. ſuec. n.* 426. *Gærtn. fruct.* 2. 115. *Huſſ. angl.* 208. *With.* 495. *Smith brit.* 514. *Curtis lond.* 1. 35. *Lightf. ſcot.* 249. *Hall. helv. n.* 1049. Dichotomous; leaves obovate: alique at the baſe, toothletted at the tip; ſtem depreſſed diffuſed.

DESCRIPTIONS, &c.

Theſe are milky plants, moſtly herbaceous, ſeveral however ſhrubby, upright for the moſt part, very few of them creeping; ſome are leafleſs, but moſt of them are leafy. Stems angular or tubercled, or more frequently cylindric or columnar; unarmed, or in the angular ſorts reſembling the upright Cactuſes and armed with prickles, which are either ſolitary or in pairs, placed in a ſingle row on the top of the ridges. Such as have leaves, have them ſimple, moſt frequently alternate and naked, in ſome ſorts however they are oppoſite and are then commonly attended with ſtipules, and in a few they are placed by threes in whorls. Peduncles in the leafleſs ſorts naked, bearing from one to three flowers; in the leafy ones axillary, but more frequently from two, to five or more in a terminating umbel; each ſometimes in a many-flowered head, but more often dichotomous, trichotomous, or even tetrachotomous, with ſingle flowers between the diviſions; at the baſe and in the forkings having bractes in number the ſame with the peduncles, forming a ſort of involucre.

Juſſieu doubts whether each ſtamen being jointed, and accompanied with chaffs, and breaking forth at different times, may not (as in Box) be conſidered as ſo many one-ſtamened male flowers encircling one female flower in a common calyx or involucre. If ſo, the flowers of Euphorbia ſhould be regarded as compound; and the plants as belonging to the claſs Monoecia *.

The juice of every ſpecies of Spurge is ſo acrid, that it corrodes and ulcerates the body wherever it is applied; ſo that it is ſeldom uſed internally. Externally it is dropped on warts or corns to remove them; and in the hollow of a decayed tooth, to remove the pain by deſtroying the nerve, or it is rubbed behind the ears to give relief in the tooth-ach by bliſtering †.]

1. Stem triangular, compreſſed, ſucculent, riſing to the height of eight or ten feet, and ſending out many irregular ſpreading twiſting branches, for the moſt part three-cornered, but having ſome two, and others four angles; at their extremities are a few ſhort roundiſh leaves, which ſoon fall off; and near theſe come out now and then a few flowers, which have five thick whitiſh petals, with a large three-cornered germ in the centre; they ſoon drop off without producing ſeeds.

It grows naturally in the Eaſt Indies, whence the plants were brought to the gardens in Holland, and thence communicated to moſt of the curious gardens in Europe. [Mr. Miller cultivated it at Chelſea, in the year 1731 ‡.]

This has generally been taken for the true Euphorbium, and as ſuch has been directed for medicinal uſe; but it is from the ſecond ſort that the drug now imported under that name in England is

* Juſſieu gen. † Witherig. ‡ Hort. kew.

taken. Linneus ſuppoſes the ſeventh to be the ſort which ſhould be uſed; but as they are all nearly of the ſame quality, it may be indifferent from which this drug, which is the inſpiſſiated juice of the plant, is taken.

β. Has alſo a naked three-cornered compreſſed ſtalk, ſending out a great number of erect branches, which are alſo generally three-cornered, but ſometimes four-cornered; they are armed with ſhort crooked ſpines, but have no leaves, nor have the plants produced flowers here. This alſo is a native of India.

2. In its native country, the Canary iſlands, this grows to the height of twenty feet or more, but in England it is rarely ſeen more than ſix or ſeven. The ſtem is very thick, green and ſucculent, and has four or five large angles, cloſely armed with black crooked ſpines, which come out by pairs at every indenture; it ſends out from every ſide large ſucculent branches of the ſame form, which extend to the diſtance of two or three feet, and then turn their ends upwards, ſo that when the plants are well grown, they have ſome reſemblance to a chandelier, they have no leaves, but are cloſely armed with black ſpines like the ſtem; at the ends of the branches come out the flowers, which are ſhaped like thoſe of the firſt ſort.

[According to Linneus, a ſeſſile flower comes forth below each pair of prickles, on each ſide; with a ſhorter ovate concave green bractæ. Calyx cloſed by five converging purple ſegments. Petals five placed on the outſide of the calyx, dark purple ſeſſile fleſhy, entire very obtuſe [d].

The flowers appear in march and april. It was cultivated in 1697, by the Ducheſs of Beaufort [e].

3. Stem ſix feet high, with prickles in pairs and aſcending branches. Leaves many, ſcattered, almoſt wedge-ſhaped, rounded at the tip, three inches long, quite entire, fleſhy, ſmooth. Corolla none. Calyx fleſhy, ventricoſe, red within, green without. Stamens ſhort, about forty. Native of Cochinchina, where the leaves are eaten boiled with other herbs [f].]

4. Stem roundiſh, upright, ſucculent, about three feet high, putting out ſeveral branches on the ſide, of the ſame form; the angles are armed with long ſingle, black ſpines: at the ends of the branches come out ſmall flowers, which are ſometimes ſucceeded by ſmall fruit.

[Native of the Cape of Good Hope. This was cultivated in 1731 [g].]

5. Stems roundiſh, ſwelling out in the middle, and having knobbed angles, between which come out long ſtraight ſpines; theſe ſtems are two feet high, and put a few branches from their ſide of the ſame form, at the ends of which flowers are produced, ſitting cloſe upon the angles; they are ſmall and of a yelloviſh green colour.

[This differs from the preceding in having the angles doubled and ſwelling a little: and the ſpines ſingle between the tubercles, which are placed longitudinally [h]. Native of the Cape of Good Hope. It flowers in july and auguſt, and was cultivated in 1759 [i].

6. This ſort has ſtalks and branches very like thoſe of the next, but much more ſlender; the ſpines of this are ſingle, and thoſe of the other double; and the ends of the branches in this are cloſely ſet with flowers on every angle.

[Native of the Cape of Good Hope, It flowers in june and july, and was cultivated in 1731 [k].]

7. This puts out many ſtalks juſt above the ſurface, which are thick, ſucculent and roundiſh, having eight or ten angles whilſt they are young, but as they grow old they loſe their angles and become round; the branches grow diſtorted and irregular, firſt horizontal, but afterwards turning upwards; the angles are armed with ſmall crooked ſpines; and on the upper part of the branches, in june and july, come out the flowers; they are ſmall, and of a greeniſh white. It grows naturally in Africa.

[Gerarde calls this the *poiſonous Gum Thiſtle*. He cultivated it in his garden; "his friend maſter William Martin, a right expert Chirurgion, having procured him the plants, by his ſervant that he ſent to St. Crux in Barbary, as Chirurgion of a ſhip: he could not however keep them through the winter."

8. This is a ſhrub of a cubit high, ſpreading and branchy: branches about the thickneſs of a finger, ſulcated longitudinally, in the interjacent channels are inſerted three prickles; of which the exterior are very ſhort and bent downwards, the middle one about an inch long, ſubulate, ſpreading and curving downward. The flowers ſpring by threes from the boſoms of the prickles, and are ſeſſile; the ſtamens ſix in number; two in each angle of the flower: the piſtil does not ariſe from the ſide, as in many others. Native of Arabia [l].]

9. Stem upright, ſtrong, five or ſix feet high, with irregular angles, and protuberances oblique to the angles; the lower part is naked, and the upper part branching, the branches are armed with crooked ſpines; at every protuberance and at the top are oblong leaves of a lucid green, very ſmooth, entire, and rounded at the end; theſe fall off in ſpring, and the plants remain naked for ſome months, and then (in june and july) the flowers come out; they ſit cloſe to the branches, and are of a greeniſh white colour; the leaves come out in the autumn.

[Loureiro adds, that the ſtem has four or five angles: that the branches are long, diffuſed unjointed; the ſtem-leaves few, at the end ſcattered, thick ſmall; and the flowers ſolitary ſcattered, ſubterminating. Native of the Eaſt Indies and Cochinchina. Much uſed for hedges, on account of its ſtrong thorns. Cultivated in 1699, in the royal garden at Hampton Court [m].

10. *Trunk* fleſhy, three inches in diameter, ſmooth: ridges eight, ten or more, broad at the baſe and keeled: keels flower-bearing, marked with ſcars of the pedunckes and with glands alternately. *Pedunckes* cylindric, the thickneſs of a pigeon's quill, jointed, with very ſhort villoſe hairs ſcattered over them, uſually firſt trichotomous, then dichotomous, ſeldom ſimple. *Bractæ* at the diviſions of the pedunckes and at the baſe of each flower oppoſite, oblong, ſharpiſh, preſſed cloſe, a line in length. *Calyx* bell-ſhaped, a little longer than the bractæ, with a five-cleft border; the clefts ovate, obtuſe, bent in, concave. *Petals* five, roundiſh-kidney-form, very blunt, twice the ſize of the clefts of the calyx, ſpreading, fleſhy, convex, green, and pierced with a few ſmall holes. *Filaments* twenty and upwards, a little longer than the calyx, ſubulate, villoſe. *Piſtil* none.—It flowers from may to ſeptember.—Native of the Cape of Good Hope. Introduced by Fr. Maſſon, in 1774 [n].]

11. This has thick, roundiſh, ſucculent ſtalks, which are ſcaly; they ſend out many branches from their ſides of the ſame form, which are twiſted, and run over one another, ſo as to appear like a parcel of ſerpents, whence it has the appellation of Meduſa's head: at the end of theſe are narrow, thick, ſucculent leaves, which drop off; and round the upper part of them the flowers come out: theſe are white, and of the ſame form with thoſe of the other ſorts, but larger; they are frequently ſucceeded by fruit.

β. Little Meduſa's head has a thick ſhort ſtalk, ſeldom more than eight or ten inches high, from which come out a great number of ſlender trailing branches, about a foot in length, intermixing and having the ſame appearance with the other, but ſmaller and much ſhorter; the ends are beſet with narrow leaves, between which the white flowers come out.

[This ſpecies was cultivated in 1731, by Mr. Miller. It is a native of Africa [o].

12. Native of the Cape of Good Hope; a perfectly ſmooth ſpecies, abounding with a milky juice,

[d] Mant. [e] Hort. kew. [f] Loureiro. [g] Hort. kew.

[l] Forſk. [m] Moriſon. [n] Hort kew. [o] Ibid.

which

which seems scarcely acrid: stem and branches erect and round; gradually thickening upwards till they arrive at the diameter of an inch: leaves sessile, spatule-shaped and elongated; very entire, and about four inches long; with a prominent back-rib: peduncles one-flowered, axillary, solitary; coated with lanceolate bractes: at the tops there are four or five larger bractes, forming a bell shaped involucre, in which is contained a sessile flower with a pale yellow calyx, and bright green petals; anthers twin on each filament: style long and upright [p].

Native of the Cape of Good Hope. Introduced by Fr. Masson in 1774. It flowers from january to auguſt [q].

13. This is one of the smaller shrubby species, and has a scaly and tuberous branched stem; the petals are each three-toothed; the leaves are extremely small, and are chiefly produced toward the tops of the branches; they are but few in number, and resemble in some degree those of the Herniaria hirsuta: the flowers are large in proportion to the plant, and spring to the number of three or four, from the top of some of the upper branches: the branches in this species are covered over with prominent tubercles or thick scales.

[Native of the Cape of Good Hope. Cultivated in 1731. It flowers in september and october [r].]

14. Stems many taper succulent, about four feet high, and requiring support; they have a light-green bark, and their lower parts are naked, but their upper parts have oblong smooth entire leaves, placed alternately on every side: flowers in small clusters at the ends of the branches, of a yellowish green colour, and sometimes succeeded by smooth round fruit, but the seeds rarely ripen in England. It grows naturally on the African shore in the mediterranean; [and was cultivated in 1732, by James Sherard, M. D. at Eltham [s].

15. Native of Madeira and the Canary islands, whence it was sent by Masson, and introduced in 1777 [t].

16. The whole of this plant is smooth. Stem erect, unarmed, jointed, purplish: branches dichotomous, covered with leaves at bottom. Leaves sessile, the length of the joints, sharpish, the lower ones erect, the upper ones spreading. Stipules roundish, minute, pale, ciliate. Flowers at the ends of the branchlets, axillary and at the divisions, solitary, small, peduncled. Peduncles shorter than the leaf. Calyx smooth, the throat whitish with close villose hairs. Petals five roundish. Capsule nearly the size of a Coriander seed, smooth and quite even. Native of the Caribbee islands.

17. Stem woody at the base, round and smooth at bottom, striated angular and subhirsute above: the two lower branches opposite, shorter than the stem, the upper ones alternate. Leaves petioled, very smooth, veinless; the two lowest opposite, oval, the rest alternate, linear, attenuated to both ends, an inch and half in length, the uppermost larger. Peduncles from the top of the stem and branches, in fives or thereabouts, umbelled. Calyx smooth, as is also the throat. Petals obovate, truncate, yellowish-green. Capsules smooth, quite even, the size of a small pea. Native of the island of Dominique; communicated by Monf. Thouin.

18. Stem unarmed: branches round, smooth, with an ash-coloured bark. Leaves petioled, several from the tubercles of the branches, unequal, smooth, veinless, quite entire. Peduncles at top, from the same bud with the leaves, round, smooth: flowers on lateral, horizontal pedicels, having a scale or two at the end. Calyx smooth. Petals obovate, truncate. Capsule villose: the pedicel scarcely beyond the calyx. Native of Arabia Felix [u].

19. Native of the Canary islands, whence it was introduced by Masson n 1779 [x].]

20 Stem taper succulent, eighteen or twenty feet high, sending out many branches of the same form, subdividing into many smaller: they are jointed, but at a great distance, smooth, and of a deep-green colour, having a few small leaves at their extremities, which soon fall off. As the plants grow older, their stalks become stronger and less succulent, especially towards the bottom, where they turn to a brown colour and become a little woody. The branches grow diffused and intermix with each other, forming a sort of bush towards the top. It does not produce flowers here. [Native of the East Indies. Cultivated in 1731, by Mr. Miller [y].

21. This is a wandlike suberect plant, six feet high, the whole of it abounding in a white bitterish milky juice. Stems numerous, round, smooth, weak, very pliant, branched, the thickness of a finger or of the thumb, the older ones ash-coloured, the younger green. Leaves some obtuse others acute, coriaceous, quite entire, petioled, deep-green, two or three inches long, deciduous except on the branches, the middle dorsal nerve and the petiole augmented by a longitudinal lamella more or less waved and conspicuous, at first frequently tomentose on both sides, but with the upper surface very even, and the edges extremely waved; afterwards both sides always become flat and smooth. Peduncles one-flowered, short, aggregate about the extremities of the branchlets, coming out principally when the plant is without leaves. Flowers void of scent, of a beautiful scarlet colour, and on account of their singular structure perhaps claiming a right to be a distinct genus, though this species has most characters the same with the other Euphorbiums. Calyx two leaved, two valved, falling off as the flower opens; the leaflets, ovate, concave, acuminate, of the same colour with the corolla; which is one-petalled, irregular, four-parted, the upper segment subtriangular, emarginate, obtuse, incumbent, the two lateral ones oblong, obtuse, produced forwards, converging, double the length of the upper one, the fourth very small, oblong, obtuse, placed between the lateral parts below the upper one. Nectareous glands four, roundish, seated in the hollow of the corolla formed of the upper segment and the united part of the lateral ones, two of these are at the base of the upper segment, and the two others close the side of the former. Filaments about sixteen, awl-shaped, unequal. Germ ovate, hanging on the outside of the corolla by a very long pedicel; style awl-shaped, longer than the germ, permanent: stigmas three, reflex, half-two-cleft.

In South America, a strong decoction of this plant, especially of the stalks, is given in venereal cases, and in suppressions of the menses.—Native of the Caribbee islands and the neighbouring continent [z].]

Mr. Miller makes two species of this under the names of Tithymalus myrtifolius and laurocerasifolius (myrtle-leaved and laurel-leaved Spurge) The first of these grows naturally near Carthagena in America, whence Mr. Robert Millar, surgeon, sent the branches, which were planted here, and succeeded: this rises with shrubby succulent stalks to the height of twelve or fourteen feet, which are too weak to stand without support, though they are frequently as large as a man's little finger; but their leaves being succulent, are so heavy as to weigh down the branches if they are not supported. The leaves are oval, and terminate in acute points; they are two inches and a half long, and one inch and a half broad near their base; they are about the thickness of Bay leaves; and are ranged alternately on two sides of the branches, to which they sit close. The flowers are produced at the end of the branches three or four together; they are of a scarlet colour of one petal in shape of a slipper.

β. The second grows naturally in Barbadoes, and most of the other islands in the West Indies, where the English inhabitants know it by the title of Poi-

[p] Jacquin. [q] Hort. kew. [r] Ibid. [s] Ibid.
[t] Ibid. [u] Vahl. [x] Hort. kew.
[y] Hort. kew. [z] Jacquin.

son

ſon Buſh: this has thick, ſhrubby, ſucculent ſtalks, which will grow to the height of ten or twelve feet; theſe are larger than thoſe of the firſt ſort, and are garniſhed with oblong oval leaves ending with blunt points; they are above three inches long, and an inch and a half broad in the middle, of a very thick conſiſtence, and of a dark green colour, ranged alternately on two ſides of the ſtalk. The flowers grow at the end of the branches; they are ſhaped like thoſe of the firſt ſort, and are of a deep red colour.

This whole plant abounds with an acrid milky juice, which will draw bliſters on the fleſh wherever it is applied, and if it mixes with the blood, I have been credibly informed, it becomes a deadly poiſon; ſo that if the points of arrows, or the edges of ſwords are rubbed with this juice, it becomes fatal to any animal wounded with thoſe weapons.

[It was cultivated in 1732, by Sir Charles Wager[a].]

22. This is an annual plant, from two to three feet high. Some of the leaves are narrow and intire, others ovate; and divided in the middle almoſt to the midrib, in ſhape of a fiddle; they alſo vary in colour, ſome being inclinable to purple, others of a light green; their foot-ſtalks are ſhort. The flowers are produced in ſmall umbels at the ends of the branches; they are of a greeniſh white, and are ſucceeded by ſmall round capſules. It grows naturally at La Vera Cruz, whence Dr. Houſtoun ſent the ſeeds.

[Moriſon ſpeaks with admiration of the heterogeneous leaves in this plant, a circumſtance which is ſince found not to be uncommon particularly in the plants from the South ſeas. He ſpeaks of this ſpecies of Spurge as attaining the height of a man, even in this country, with a trunk an inch in thickneſs and more, ſpreading out into ſtraight, long, pliant branches; having ſome leaves three or four inches long, and narrow, reſembling thoſe of the narrow-leaved willows, others on the ſame branch ſoft, like thoſe of an Atriplex or Orach, tending to a ſea-green colour, ſinuated, and from an inch to near two inches in breadth, others again very long and narrow. Varieties are obſerved in this plant, ſome having a reddiſh and ſomewhat wrinkled bark, whilſt in others it is green and ſmooth, the leaves alſo being ſubject to vary much; as might be remarked in the royal garden at Hampton Court, where this Spurge was cultivated in 1690[b]. This being ſhrubby, and ſo large a plant, cannot be the annual ſpecies of Miller deſcribed above. It belongs, as Retzius has obſerved, to the third ſection.]

23. Stem upright, ſix or ſeven feet high, covered with a light brown bark, and dividing at top into many branches. Leaves ſmooth, and of a beautiful green, but falling away in winter. Flowers from the ends of the branches, yellow and ſmall, ſoon falling away without fruit. Native both of the iſlands and continent of South America. Mr. Miller received it from Tobago and Carthagena, and the Dutch gardens have it from Curaçoa. [It was introduced in 1690 by Mr. Bentick[c].]

24. This is an annual plant, riſing with an upright ſtalk about a foot high, and dividing into a great number of branches, which, ſpread very wide on every ſide. Leaves roundiſh-heart-ſhaped, on pretty long foot-ſtalks. The flowers come out ſingly from the diviſions of the ſtalk; they are ſmall, of an herbaceous colour, and are ſucceeded by ſmall round capſules. Native of South America: the ſeeds were ſent to Mr. Miller from La Vera Cruz, by Dr. Houſtoun.

[25. The whole of this is ſmooth. *Stem* unarmed: branches dichotomous at the end, three and four times divided. Leaves on ſhort petioles, longer than the internodes, ſhorter and narrower on one ſide of the baſe, terminated by a minute dagger-point, even, veinleſs, glaucous-green. Peduncules at top from the forks of the branchlets, ſolitary. Flowers ſmall. Capſule ſmooth, even, the ſize of a Coriander ſeed. Native of the Eaſt Indies[d].

26. This is ſo like Marjoram, that it cannot but be taken for it at firſt ſight. It is a native of the iſland of Aſcenſion[e], and the Friendly iſles.

27. This alſo is a native of the Friendly iſles[f].]

28. This is an annual plant, which riſes with a branching ſtalk about two feet high, [herbaceous diffuſed, ſubdivided, round, coloured, ſmooth; branches alternate, ſpreading, pubeſcent. Leaves petioled, oppoſite, oblique at the baſe, ovate, obtuſe, veined, glaucous underneath, ſometimes purpliſh. Stipules ſimple, oppoſite, very ſhort, blunt, between the petioles. Peduncules axillary, alternate, erect, dichotomous, commonly longer than the leaves, with the flowers crowded together. Calyx very minute. Petals four, convex thick, green. Filaments two or three, longer than the corolla (not many breaking out at different times) with rudiments of others at the baſe. Anthers in pairs (like bifid filaments) yellow. Germ ſmooth. Capſule pedicelled. Native of moſt of the iſlands in the Weſt Indies, a weed in cultivated grounds[g]. Every part of it is poiſonous to hogs[h]. Cultivated in 1739 by Mr. Miller.

29. Native of Madeira, where it was found by Mr. Francis Maſſon. Introduced in 1784. It flowers in april and may.

30. Stems herbaceous, a ſpan in length, procumbent, round, branched, red. Leaves oppoſite, on very ſhort petioles, blunt iſh, ſmooth, obſcurely three-nerved, the upper ſurface green, the under glaucous. Flowers on ſhort pedicels, often in threes, but ſometimes ſolitary. Petals purple. Native of the Weſt-Indies. Cultivated by Mr. Miller in 1758[i].

31. An annual; acrid and milky; flowering in gardens in the open air, and readily ſpringing from ſeed: ſtems very numerous, ſpreading cloſely on the ground: leaves oblong, obtuſe, and ſometimes acute; obſcurely denticulated on the ſuperior part, ſmooth on the ſurface, but edged with hair on the back and margin: extremely numerous; and either green, red, or even deep purple; and ſometimes ſpotted; thickly crowded on the tips of the branches in particular: flowers very ſmall, on very ſhort foot-ſtalks, from the boſoms of the leaves: calyx green; petals red, capſule hairy. Native of the iſland of Jamaica[k].

Cultivated before 1668, by Mr. Walker[l].

32. Stem herbaceous, ſubdivided, declined, from three inches to a foot in length, round. Leaves on very ſhort petioles, oppoſite, ſmall, oblique at the baſe, nerved, rough with hairs, paler underneath, ſpotted with red. Stipules in pairs, oppoſite, awl-ſhaped. Peduncules oppoſite, very ſhort, much ſhorter than the leaves; flowers crowded together, pedicelled, minute. Calyx blood-red. Petals four, truncate, thick, blood-red. Filaments four, and not more, awl-ſhaped, from the bottom of the calyx, longer than the corolla. Anthers roundiſh, whitiſh, two-valved. Germ rough with hairs[m]. Native of both Indies. Browne recommends it as a powerful reſolutive and deobſtruent, provoking both ſweat and urine very abundantly.

33. This is ſmaller and much more tender than the foregoing. Stem ſimple, round, covered with reddiſh-brown hairs, and half a foot in height. Leaves oppoſite, bluntly and ſcarcely ſerrate. Peduncules an inch long, coming out alternately from the axils, bear two heads of flowers together. Theſe are both annual. Native of India[n].

34. Native of the Weſt-Indies. Introduced in 1787, by Mr. Alexander Anderſon. It flowers in auguſt and ſeptember. Annual[o].

Browne extolls a decoction of it as an active warm medicine, after a paſſage is procured in the dry belly-ache, by bathing in warm water, or on

[a] Hort. kew. [b] Mor. hiſt. [c] Hort. kew. [d] Vahl. [e] Linn. ſpec. [f] Foſter. [g] Swartz. [h] Sloane. [i] Hort. kew. [k] Jacquin. [l] Hort. kew. [m] Swartz. [n] Burm. zeyl. [o] Hort. kew.

any

any occaſion where reſolutive medicines are required.

35. Stem ſlender, ſomewhat hairy, breaking out near the ground into many very ſlender branches, half a foot long, alternate, ſubdividing into others. Leaves at the joints and diviſions of the ſtem and branches, very ſmall, ſeſſile. The whole plant reſembles Thyme. Native of India. Annual[b].

36. Stem upright, round, ſmooth, green. Leaves oppoſite, ſome entire, others ſlightly and obtuſely ſerrate, ſmooth on both ſides. Peduncle axillary, an inch long, alternate, ſuſtaining a very few ſmall flowers[c].—The leaves have frequently a brown ſpot. Calyxes purple. Petals white[d]. Annual. Native of India.

37. Very nearly allied to *E. Chamæſyce*, but the whole every where villoſe-white. Leaves ſlightly emarginate and obſcurely notched[e].

Since this varies with ſtems almoſt ſmooth, and with leaves either ſlightly crenulate or entire, Cavanilles is of opinion that the next is not ſpecifically different from it. According to him, the ſtems are a ſpan high, red, covered with white hairs, with alternate branches. Leaves oppoſite, on very ſhort petioles, lens-ſhaped, margined, narrower at the baſe in front, with a brown ſpot in the middle. Flowers ſubſeſſile between the ſtem and the branch. Petals four, very ſhort, calloſe at the baſe, with a white border obſcurely three-notched. Filaments ſhort, inſerted into the receptacle, coming out at different times, uſually two together: anthers ovate. The pedicel of the germ increaſes gradually: ſtyles ſo ſhort, as to be hardly viſible[f].

Annual. Native of Spain, particularly in the province of La Mancha.

38. Stem depreſſed. Leaves oppoſite, emarginate, the baſe narrower in front. Flowers from the dichotomy. Calyx ruſous. Petals white, crenate. Fruit ſmooth, annual[g].

Stems herbaceous, from two to four inches long, round, purpliſh. Branches dichotomous, ſhort, thoſe which bear flowers procumbent. Leaves petioled, oppoſite, ſmall, veined, dotted, purpliſh-green, glaucous underneath. Flowers very minute, crowded, ſubſeſſile. Teeth of the calyx white-ciliated. Petals between theſe, blood-red. Filaments two or three (not more) very minute. Anthers black. Germ bent down: ſtyles blood-red. Seeds roundiſh-angular, black[h].

South of Europe, eſpecially in the kingdom of Valencia in Spain: alſo in Siberia, and Meſopotamia; and by way ſides and barren fields in the Weſt-Indies.

Cultivated in 1752, by Mr. Miller[i].

39. Root annual. Stems herbaceous, an inch and half high, very ſmooth, dark red, as is the whole plant. Leaves ſeſſile, ſeldom green. Involucre three-leaved; leaflets orbiculate, mucronate, three times as large as the ſtem-leaves. Calyx turbinate, very ſmall. Petals red, horned. Capſule ſmooth ovate. Seeds whitiſh, with red grooves. Native of Spain, near Aranjuez, flowering in april and may[k].

40. This has the habit of E. Chamæſyce. Stems ſeveral, woody, filiform, diffuſed, dichotomouſly branched, purpliſh, ſcarcely hairy. Leaves on ſhort petioles, only half the ſize of thoſe in E. Chamæſyce, thickiſh, appearing hairy with a magnifier, narrower on one ſide of the baſe. Flowers pedunculed, very minute: peduncles only half the length of the leaf. Capſule leſs than a muſtard ſeed, ſomewhat hairy[l].

41. Root long, ſlender, fibrous. Stem forked immediately from the root: branches trailing, again forked of irregular lengths, frequently purple. Flowers on peduncles. Seeds ſmooth, tipped with purple[m].—According to Scopoli, ſtem round. Edges of the leaves purple. Petals red, roundiſh.

According to Vahl, ſtems a foot high, ſmooth, as is the whole plant; the internodes an inch and half long: branches alternate, dichotomous, frequently divaricate. Leaves oppoſite, petioled, thickiſh, veinleſs, narrower on one ſide, and ſhorter towards the baſe, broader on the other, widened at the baſe into an earlet, which is frequently toothletted. Capſules ſmooth.—Annual, flowering in july and auguſt.

Native of the South of France, Spain, Carniola, England, on the ſea-coaſt. Between Penzance and Marketjeu in Cornwall. Near Exmouth in Devonſhire. It is called by Gerarde Hope Spurge.

42. Annual. Native of Maryland and Virginia. It has the ſtature and appearance of Chamæſyce, but the leaves have a lobe at the baſe on one ſide. Stems procumbent, dichotomous and divaricating[n].

43. Stems herbaceous; upright but weak, entirely green, dichtomous, tender, from two to three feet high. Leaves acute, ſhining, an inch and half long, few, on petioles an inch in length. Peduncles terminating, upright, ſlender. Calyx bell-ſhaped, hirſute within. Petals two, roundiſh, quite entire, white. Capſules ſhining, ſmooth, ſmall. Native of Carthagena in New Spain, in wet graſſy places[o].

Swartz has deſcribed a plant under the ſame name a native of Jamaica: but he doubts whether it be the graminea of Linneus. His deſcription certainly does not agree with that of Jacquin given above.

44. Root creeping. Stems a ſpan high, erect, dichotomous. Leaves oppoſite (only one or two of the loweſt alternate), lanceolate, even, quite entire, the length of the internodes. Peduncles axillary, ſolitary, one-flowered, the length of the leaves whilſt in flower, but twice as long when in fruit. Calyx thick. Native of Virginia and Canada.

45. Stem erect, a ſpan or a foot high. Leaves oval, quite entire, ſmooth, the ſize of Purſlain leaves or larger, (one or two of the loweſt only alternate), obtuſe, obloletely emarginate. Stem dichotomous, in the firſt diviſion ſometimes trifid and three-leaved. Peduncle long, as in the preceding. Native of Philadelphia[p].

46. Stem ſhrubby, from one to two feet high, very much branched, round, ſmooth: branches almoſt filiform, long, ſubdivided, thickened at the petioles, ſmooth, red. Leaves oppoſite, ſmall, the lower ones orbiculate, the upper abovate, or oblong or roundiſh, ſmooth, glaucous underneath, flat, ſpreading; on very ſhort red petioles. Flowers minute, axillary, eſpecially towards the ends of the branches; on very ſhort peduncles. Calyx four, or five-toothed, hirſute within. Petals four, thick, roundiſh, depreſſed, yellow. Filaments two, very minute: anthers roundiſh, whitiſh, large. Germ bent down: ſtyles reflex: ſtigmas ſimple, acute. Some of the flowers are barren, and have a cylindric germ, a ſingle ſtyle, which is long and trifid at top. Native of Jamaica, on the cooler mountains[q].

47. This is a ſmall ſhrub, a hand or little more in height, branched at the baſe: branches ſimple, round, covered with leaves, toothletted where the leaves fall, ſmooth, as is the whole plant. Leaves ſeſſile, crowded, wedge-ſhaped, ſmall, mucronate, toothletted at top, but at bottom quite entire. Umbel terminating, twice biſid. Involucres five-leaved, oblong, quite entire: involucels two-leaved. Petals quite entire. Stamens numerous: filaments whitiſh. Native of Portugal[r].

48. Root annual. Stem upright, nine inches high, round, ſmooth and branched; at bottom harder, more ſlender, and of a reddiſh colour, leafy and milky: branches few, not growing in any regular order, the lower ones longeſt. Leaves on the ſtem alternate. Involucres obovate. Involucels cordate, rounded and obtuſe at the end. Petals (or

[b] Burm. zeyl. [c] Ibid. [d] Linn. ſyſt. [e] Linn. ſpec. [f] Cavanilles. [g] Linn. Mant. [h] Swartz. [i] Hort. kew. [k] Cavanilles. [l] Vahl. [m] Woodw. Mſs. [n] Linn. ſpec. [o] Jacquin. [p] Linn. amoen. [q] Swartz. [r] Vahl.

nectaries) four, yellowish green, crescent-shaped. Stamens seldom more than two or three visible together, beyond the calyx. Capsule smooth (or scabrous at the edge [a],) small, roundish-three-cornered, having two membranaceous, waving, very narrow crests or keels at the corners, perforated below the top, of a papery substance, two-valved. Receptacle columnar, central, slender, terminated by a depressed spongy head. Seeds ovate, on one side convex and scrobiculate, in rows, on the other angular, with a middle ridge, whitish-ash-coloured, with a conical fungose solid white umbilicus at top [b].—According to Linnæus, all the flowers are hermaphrodite; but Retzius affirms that it is often polygamous, with one or two flowers on an upright pedicel, bearing petals, style and stigmas, but no germ or anthers.

Native of most parts of Europe, in kitchen gardens and other rich cultivated soil: flowering in july and august.

It may easily be distinguished from *E. helioscopia*, which has some resemblance to it, and is frequently found with it, by having the leaves entire about the edge, and the petals furnished with a horn at each end [c].

β. This variety has ovate-lanceolate, sharp leaves. The involucre is of the same form with the leaves; but the involucels are obliquely cordate [d].

In Savoy, about Montpellier, &c.

49. Very nearly allied to the next species. It differs from it, however, in having the leaves broader, of a lanceolate form, and blunter: the involucels manifestly cordate-sickle-shaped, mucronate: the divisions of the umbel more dichotomous: the stem less branched, and a little higher [e].

According to Villars, it is very low and much branched, the stem-leaves fall immediately, it retains only those of the divisions, which are repeated several times, spread out and bent back in such a manner, that the whole plant resembles a little bush; the elliptic petals have two very small threads, and sometimes only one; fruit smooth, and a little prolonged.

Native of the South of France, Switzerland, Germany, Austria, &c.

50. Root annual. Stem upright, branched, very leafy, about six inches high. Branches from the lower part of the stem. Leaves pressed to the stem, ending very sharp. Umbel trifid, quadrifid, seldom quinquifid, dichotomous. Involucres lanceolate-linear; involucels ovate-oblong, acuminate, opposite, often irregular. Calyx smooth. Petals or nectaries four, each furnished with two little horns. Stamens (from five to nine) generally about two visible [f]: the filaments swelling out into a globular form close under the anthers [g]. Capsule smooth [h].

This small and delicate species is found in cornfields in many parts of Europe; flowering from july to september.

β. Linnæus affirms that this species is sharp-leaved on hills, retuse in meadows. Cavanilles on the contrary says that he has found the latter on sandy hills, and the former in corn-fields: and Krocker has observed them both in corn-fields. Cavanilles separates them, because in E. retusa the corolla is five-petalled, and the leaves emarginate at the end. This is found about Montpellier, in Spain and Silesia.

Professor John Martyn, in his edition of Tournefort's history of plants about Paris, says that there is a Spurge growing abundantly all over Cambridgeshire in the corn, differing from *Tithymalus f. Esula exigua, Bauh. pin.* only in having the leaves blunt at the end; which he is persuaded is what Mr. Dent inserted in the appendix of the Cambridge catalogue, and Mr. Ray received into his synopsis and history under the name of *T. Jegetum longifolius*; perhaps (say he) it may be *T. f. Esula exigua foliis obtusis*. Bauh. pin. &c. See n. 72.

51. Stems hirsute. Leaves attenuated at the top. Native of Carthagena in New Spain, on the sandy coast [i], also of Jamaica.

[a] Curtis, Linn. fuec. Retz. [b] Gærtner. [c] Curtis. [d] Retz. [e] Krocker. [f] Curtis. [g] Withering. [h] Linn. [i] Jacquin.

52. Root tuberous. Leaves nearly an inch and half in length, and almost half an inch in breadth, on petioles two or three inches long, springing from the root; they are blunt at the end, and sometimes emarginate. The stems are scarcely a hand and half in height, naked, dividing at top into two peduncles, each sustaining two flowers; there are two leaves at the division. Capsules large, hairy. Native of Africa [a].

53. Native country unknown: a smooth lasteſcent species: stem and branches shrubby, round; the older ones ash-coloured, the younger reddish-brown, marked by the cicatrices of the fallen leaves: the upper branches green: the branches are all progressively trichotomous; leaves very narrow and lanceolate, obtuse, entire, with very short foot-stalks, and very numerous; the terminating umbels are generally trifid, with dichotomous rays; the leaves forming the smaller umbels are roundish; petals four, sometimes five, dull yellow, roundish, flat, and obtuse; perianth hairy; anthers yellow-green: germ pale-green; capsule smooth [b].]

54. Stem upright, succulent, from three to four feet high, with oblong smooth sessile leaves; the upper part dichotomous, and an umbel comes out from each division; that in the first division being the largest, and those in the upper the smallest. The flowers are of a greenish yellow colour, appear in june and july, and the fruit follows soon after.

[All the involucres are cordate. There is one flower between the four rays of the umbel, which is male; the others are hermaphrodite. Filaments as far as thirty-six (Haller says thirty-eight,) but a third part of them usually abortive. Capsules smooth [c]. What Linnæus calls the petals, are in this species evidently hollow nectaries, containing juice, and putting forth a horn on each side [d]. The parts in this species being large, it is the most proper for acquiring a just idea of this difficult genus.—It is a native of France and Italy, and has been long in the English gardens; being common there in the time of Gerarde.

55. Root annual. Stem herbaceous, more than half a foot in height, round. Leaves smooth, oblique, roughish about the edge. Involucre consisting of about four leaves, which are oblong-ovate, blunt, broader than the leaves, scarcely serrate. Involucels ovate, truncate at the base. Petals yellowish, with two or three teeth. Capsules smooth. From the lower axils of the leaves proceed barren branches. In the form of the leaves it approaches near to *E. exigua retusa*, but in that they are only a line in breadth, whereas in this they are a finger broad [e]. Native of Spain, and the South of France.

56. Root annual, of a slender fusiform figure. Stem round, upright, red at the base, half a foot high, so branched from the bottom, as to have the appearance of several stems: lower branches ascending: both they and the stem almost covered with imbricate leaves. Umbels four-cleft or five-cleft, with the rays several times dichotomous; the branches are sometimes divided into a similar umbel, and sometimes are very dichotomous: hence the plant when grown up becomes so spreading, and has such an abundance of branchlets and rays as to give it an appearance quite different from what it had when young. Leaves alternate, subsessile, wedge-shaped, truncate, with a small point in the middle, quite entire, flat, not three-toothed or retuse; in the adult plant they are sometimes only blunt, without any point on the stem and principal branches, and generally fall off. Leaflets of the involucre like the leaves, the same number as the rays: of the involucels opposite, sessile, quite entire, blunt with a point, oblong, one side at the base produced towards the side, the other obliterated; in the upper divisions broader, shorter, and often retuse, sometimes two or three-toothed. Flowers all fer-

[a] Ray. [b] Jacquin. [c] Scopoli. [d] Haller. [e] Linn. Spec.

tile,

tile, ſolitary in the diviſions, ſmall, ſeſſile. Calyx ſmooth, pale. Petals four, yellow, two broader. Germ ſmooth. Seeds brown, much wrinkled. The whole plant is ſmooth. It differs from *E. terracina* in having the leaves lanceolate, not oblique, nor in the leaſt rugged about the edge. Near Vienna flowering from july to ſeptember [7].

57. This has a knobbed pear-ſhaped root, from which ariſe two or three ſtalks about a foot and half high. Leaves oblong, hairy, alternate, on every ſide the ſtalk. Flowers in ſmall umbels from the diviſions of the ſtalk, ſmall, greeniſh-yellow, ſeldom producing ſeeds here.

[The barren ſtems have linear-lanceolate, blunt leaves: on the flowering ſtems they are roundiſh-ovate. Umbel quadrifid, then biſid, and no farther. Univerſal involucre four leaved, the leaflets roundiſh, ſcarcely ſharp. The firſt involucels are obcordate, the latter reniform, ſcarcely mucronate [8]. Native of the iſland of Candia.—Cultivated in 1596, by Gerarde [9].

58. The whole plant is ſmooth. Stem ſhrubby, round. Leaves ſcattered, ſeſſile, an inch and half in length. The univerſal involucres reſemble the leaves. Involucels of the firſt diviſion oval-oblong, ſomewhat emarginate, half the length of the leaves; thoſe of the ſecond diviſion and the floral ones elliptic-roundiſh, emarginate. It flowers in june and july; and was cultivated by Mr. Miller in 1758 [1].

59. An upright ſhrub, with branches alternate, ſtrict, very ſimple, ſhort, bearing flowers at the very tip. Leaves ſomewhat crowded, ſmooth, quite entire, ſmaller than the other ſpecies, not larger than in *E. exigua*. Umbels terminating, ſeſſile. Involucre four-leaved; leaflets lanceolate, the length of the umbel. Involucels two-leaved, ovate-rhombed. Umbelled biſid, and divided no farther. Petals in form of a creſcent. Capſules ſmooth. Native of the Cape of Good Hope [2].

60. The branches as they grow old, dry away and continue on the plant, ſo that it appears as if it had thorns. The flowers are uſually ſolitary. Petals round. Capſules warted.—Moriſon diſtinguiſhes the *ragaſſinus* of Hermann from the *ſpinoſus* of Bauhin; but they ſeem to be the ſame [3].—Native of the Levant. Cultivated in 1752, by Mr. Miller, edit. 6. n. 16 [4].

61. This approaches to *E. dulcis*, but the leaves are more ſcabrous about the edge, and villoſe underneath. Capſules hiſpid, with ſubulate purpliſh briſtles ſcattered over them. Native of Italy and Auſtria [5].

62. Root perennial. Stems ſeveral, ſmooth, firm, ſomewhat woody, green or reddiſh, either ſimple, or a little branched near the umbel, but without any univerſal involucre on the branches. Leaves very ſmooth and even, firm, thickiſh, alternate, ſpreading or horizontal, almoſt ſpatulate, blunt and ſlightly reflex at the end, ſo as to appear emarginate. Umbel moſtly quinquefid, the rays twice dichotomous, the laſt diviſion two-flowered, in the axil one flower, on the extreme branches two flowers, one yellow, with horned petals and naked, the other green, ſupported with two bractes, and abortive. Capſules ſmooth, not grooved, large. Univerſal involucre ovate, terminating in a prickle; involucels cordate, or rather ſemicircular. It abounds in milk.

Vahl remarks, that it is nearly allied to the next ſpecies, but differs from it in having the leaves, involucres and involucels quite entire. The ſtems are a foot high, aſcending, round, warted. Leaves an inch long, narrowed a little towards the baſe, thickiſh, quite entire. Umbel terminating, and often one or two lateral ones. Involucre five-leaved, oblong, of the ſame ſtructure with the leaves. Involucels firmer than common in the other ſpecies, mucronate. Rays of the primary umbel three or four inches long, twice biſid.

Native of the county of Nice [6]. Found alſo by Vahl about Pampeluna.

63. Involucels very finely ſerrate. Petals entire. Fruit red, muricate. It varies with villoſe leaves [7].

Root conſiſting of little ſcaly bulbs. Stem ſmooth upright, ſimple, a foot high, red at bottom. Leaves ſcattered, ſeſſile, an inch long, obtuſe, quite entire, or very finely ſerrate. Involucres five-leaved, but ſometimes four, three, and even two-leaved. Involucels two leaved, ſubovate or cordate, unequally toothletted, yelloviſh, to which colour the whole plant is inclined. Flowers ſeſſile. Petals red, creſcent-ſhaped, two-horned. Stamens two to five. Capſule villoſe, warted below the middle. The milk is mild [8].—Native of the South of Europe. Cultivated in 1759, by Mr. Miller [9].

64. The peculiarities of this ſpecies are, that the leaves are quite entire, ſpreading, ſeſſile, acuminate, with the edge pellucid and red—that the leaves and rays of the umbel are very lax: that the colour is yelloviſh: that the flowers are all pedunculed, and moſt of them barren, except thoſe at the end: they have five roundiſh ſhining yellow petals: and the capſule is warted. The milk is mild. It flowers after the end of april.—In ſhady meadows about Idria in Friuli [1].

65. Stems ſhrubby, ſimple, many, villoſe, a foot high. Leaves quite entire, acuminate, ſeſſile. Umbels of four or five rays. The flowers from the firſt diviſion of the rays fertile, pedunculed; petals reddiſh brown, hemiſpherical. Capſules the ſize of a pea, echinated with ſoft, reddiſh prickles [2].—Native of the South of Europe. It flowers in june and july: and was introduced in 1785, by Mr. John Græfer [3].

66. Stems rather ſhrubby, a hand's breadth or more high, ſmooth, cylindric, red, eſpecially during the winter. Leaves alternate, ſubſeſſile, wedge-oblong, keeled, ſmooth, but not ſhining, red underneath at the baſe. Branchlets lateral, thoſe from the lower axils barren, at length growing up ſo as to overſhadow the ſtem. Umbels terminating, have three, four, five or ſix ſpreading rays. Involucre like the leaves, but ſhorter and broader. Involucels rhomb-heart-ſhaped. Theſe and the leaves are terminated by a ſharp point. Flowers ſubſeſſile, yellow; the firſt and ſecond male, having very blunt petals, without horns; the reſt hermaphrodite, with horned petals.—In the central flowers, the calyx has five ſides, and five blunt corners, with five ſlight cleſts, and the ſegments are more or leſs toothed at the end; the petals are hairy within; the filaments are eight or nine; and the germ is ſubſeſſile. In the lateral flowers, the ſegments of the calyx are four: the petals four; the ſtamens fourteen or more; the filaments ſurrounded at the top with a ring. In all, at the baſe of the flower, are ſeveral flat ſlender ſkinny woolly ſubſtances, cloven at the end. Fruit ſmooth, with the angles muricate [4].

Firſt found by the Rev. Mr. Stoneſtreet in 1711, in the narrow neck of land which joins Portland to Devonſhire. Since that near Exmouth in the ſame county. Abundantly on the ſhores of Cornwall: and near Caernarvon in Wales. It flowers from may to ſeptember. Marked as a ſhrub by Linneus: as perennial in the Kew catalogue, and by Smith; and as annual by Hudſon and Withering. It abides two or three years in gardens.

67. Native of Auſtria; in ſtony places: ſtems five or ſix inches long, procumbent, and but very few in number: ſmaller or ſecondary branches more numerous; each terminated by a roſe of leaves, while the older or lower leaves fall away in ſucceſſion, ſo as to leave numerous ſcars; branch leaves lanceolate; top and flower-leaves round-cordate; all ſeſſile. Flowers ſmalliſh and yellow: the plant is glaucous, except the bractes or round leaves ſupporting the flowers [5].

[9] Hort. kew. [1] Scopoli. [2] Ibid. [3] Hort. kew.
[4] Linn. Withr. Stokes in Withr. [5] Jacquin.

68. Of a glaucous or sea-green colour. Root perennial. Stems upright, or ascending, numerous, generally red at bottom, thickly imbricated with smooth fleshy leaves, pointing upwards when wild, but open when cultivated, gradually increasing in size from the lower part of the stem upwards; the lower ones linear, linear-lanceolate, or oblong, sessile; the upper ones oval-lanceolate, half-stem-clasping. Involucre of five heart-shaped leaves. Petals entire. Capsules very large, smooth[1]; but according to Dr. Withering, rough: all others say smooth.

On the sandy shores of Europe: with us on the coasts of Essex and Kent; between Southwold and Dunwich in Suffolk; Cornwall. Flowering in august and September.

The juice of Sea Spurge is highly acrid; according to our Gerarde it is the most so of any species. He relates, that putting a single drop into his mouth, his throat inflamed so, that he hardly escaped with his life, by riding to the next farm-house, and drinking milk.

69. Perennial. Flowering in july. Native of the island of Porto Santo near Madeira. Found there by Mr. Francis Masson. Introduced in 1779[2].

70. Root perennial, creeping, by which it multiplies very fast where it is once established. Stems a foot and half high. Lower leaves narrow, stiff and bristly, the upper ones shaped like those of narrow-leaved Myrtle. Flowers in large umbels from the divisions of the stem, yellow, appearing in june, but rarely producing seeds in this country. Native of Aleppo, and other parts of the Levant.

[71. There is no description of this, nor is it known where it is a native.

72. Root annual. Petals crescent-shaped. Fruit smooth, except that it is scabrous at the corners. Umbel often the length of the whole plant. Involucels almost semiorbiculate. There are flowering branches below the umbel[3].

According to Villars, it is from six to ten inches high; the lower stem-leaves fall very soon, and sometimes barren branches spring from the bottom of it; the umbel is divided into four parts, and each branch is subdivided into two, four or five times over; involucres triangular and blunt: petals ending in two short threads, less distant from each other than common; fruit three-cornered, smooth, except near the angles, where it is a little rugged.

Native of Barbary and Russia, of the South of France, Austria, Silesia, and the county of Nice.

Linnæus, Gerard, &c. quote the *Tithymalus segetum longifolius* of Ray, as a synonym of this species. Mr. Hudson, following Dillenius, makes this a variety of the *platyphyllos*. I once thought that our Cambridgeshire plant was the *segetalis*; but we have no other besides the *exigua*. See n. 50.

73. Root annual. Stems eight or ten inches high, erect, smooth, round, red at bottom. Leaves scarcely petioled, hanging down a little, very smooth, paler underneath, blunt at the end with a point, but the first leaves sometimes emarginate. They are about two inches asunder, and from each axil proceeds a naked flowering branch. The terminating umbel has generally four rays, three or four inches in length, naked, and dividing again into pairs. Where these divide a single flower sits on a peduncle about an inch in length. Petals crescent-shaped.—It approaches to *Euph. segetalis*, but is much more branching, the branches coming out from the very lowest axils. The leaves are pale green, of a less firm substance. The leaves of the universal involucre are broader, and hang down. The whole plant has the branches and rays of the involucre divaricated. Whereas in *E. segetalis* the stems are firm and upright. The leaves narrower, somewhat glaucous, thicker, more crowded, and reflex, less deciduous. The umbel of five or six rays. In the manner of flowering and seeds they agree. The fruit in this is smooth, except at the angles.—Near Lusenzo, not far from Aosta; and near Guillestre in Dauphiné: flowering from the beginning of april to the end of june[4].

74. Root annual. Stem upright, from six to nine inches high, round, slightly hairy, having opposite branches at bottom. Leaves alternate, or scattered, few, smooth, the lower petioled, the upper sessile. Umbel spreading, fastigiate. Involucre of five leaves, like the other leaves. Involucels three, unequal, the inner only half the size of the others. All the flowers hermaphrodite. Calyx greenish yellow, with four or five yellow segments. Petals, or nectaries four, entire, roundish, or oval, yellowish green. Filaments fourteen; two, three or more visible at a time. Capsule smooth[5].

Native in most parts of Europe, in cultivated grounds. It flowers from july through the autumn. Called by the country people *Wart-wort*, *Churn-staff*, and *Cat's-milk*.

The juice is very acrimonious, and hence is often applied to warts for the purpose of destroying them. It should be used with caution, where the parts are tender, particularly near the eyes, as it will inflame the face to a great degree[6]. According to Linnæus, if sheep eat it, they are purged by it, and their flesh acquires a bad taste; but this is not the case with cows.

75. Root annual. Involucels of the secondary and last umbel three-leaved; two leaflets broader on one side, oblique at the base, narrower on the other side, on the outside a little dilated towards the base; the third leaflet is ovate-roundish, with equal sides. Having the leaves and manner of growth the same as in E. helioscopia, at first sight it appears to be the same plant; but it differs in having the top of the stem, the leaves, peduncles and pedicels villose, and the capsules muricated with small tubercles. In cultivated grounds about Tunis[7].

76. This is a foot high, and is easily known by its oblong leaves, with frequent and sharp serratures[8]. The leaves, however, vary very much, being sometimes cordate on the flowering-stems, and linear on the branches and barren stems, and sometimes linear on all. The umbels also are sometimes three-rayed and bifid, with the involucres and involucels cordate-attenuate[9].

Native of the South of Europe. Introduced in 1780, by Sign. Giovanni Fabroni[10].

77. Root biennial. Stems from eight inches to a foot in height, simple, cylindric, decumbent. Leaves ovate-lanceolate, half-stem-clasping, finely serrate, a little villose. Fertile branches axillary, dichotomous. Umbels small, yellow, spreading, extending above the stem. Involucre five-leaved, lanceolate, obscurely serrate. Involucels subovate, very entire. Flowers of the first, second and third rank abortive. Petals four, entire, yellow. Capsule very much warted[11].

Corn fields in the South of Europe and the Levant: flowering in july.

78. This most splendid plant, by far the most beautiful of the genus, is the height of a man. the stem shrubby, rather fleshy, full of milky juice, round, abruptly branched: the branches curved upwards, three together; the smaller branches sometimes four or five together: bark smooth, whitish, marked with spots or scars where former leaves have grown. Leaves on the summits of the smaller branches, crowded together, almost sessile, spreading in every direction, bluntish, ending in a small point, smooth, opaque, dark-green, glaucous underneath; the younger ones turned inwards, and those nearest the umbels coloured: principal nerve of all the leaves dull yellow, and in the younger ones near the umbels it is besides stained with red. Umbels terminating, erect, having five, six, or seven rays. Peduncles club-shaped, smooth, dichotomous. Involucels

[1] Woodw. Ms. Linn. [2] Hort. kew. [3] Linn. [4] Allioni. [5] Linn. Curtis, Withering. [6] Curtis. [7] Vahl. [8] Villars. [9] Vahl. [10] Hort. kew. [11] Linn.

lucels two or three together under each flower, of a moſt vivid ſcarlet. Flowers ſolitary, turbinate, yellowiſh, ſoon turning reddiſh. Calyx five-toothed. Petals five, divaricated, yellow, full of very ſweet pellucid honey. Stamens fifteen or twenty, fertile, many abortive. Germ reflex. Styles reflex, red. Receptacle occupied by chaffy branched filaments. Capſule ſmooth.—Diſcovered in Jamaica, but ſparingly, by Matthew Wallen, Eſq. who ſent it to the late Marquis of Rockingham in 1778[a].—It flowers in january.

79. Stature erect. Univerſal umbel five-cleft, primary partial umbel three-cleft, the others dichotomous. Univerſal involucre five or ſix leaved, leaflets oblong, obtuſe; partial three-leaved, the reſt two-leaved. The rays of the primary umbel have a leaflet and a ſmaller dichotomous branch in the middle. Stem-leaves lanceolate, very obtuſe. Petals ſnow-white, ſpread out flat, in fives, not ſhaped like a pelta, but very ſlender[b].

Native of Virginia and Canada.

80. Stems quite ſimple, annual, round, ruſh-like, upright. Leaves broad-lanceolate, bluntiſh, ſeſſile, alternate, quite entire, villoſe underneath, often ruſeſcent at the edge. Univerſal umbel five-cleft, partial three-cleft, then dichotomous. Univerſal involucre five-leaved, partial three-leaved then two-leaved; leaflets ovate-oblong; in the laſt ovate, all ſomewhat hairy. Petals four, entire. Capſules globular, ſcarcely grooved, covered with a thin, long, white wooll[c].

Native of Sicily, Barbary and the Levant. Cultivated in 1739, by Mr. Miller[d].

81. It has entirely the air of *E. paluſtris* (n. 90), inſomuch that it might eaſily be taken for the ſame plant; it flowers alſo at the ſame time; it is, however, a little larger.—Root perennial. The leaves are broad-lanceolate, alternate, ſcarce apparently hairy on both ſides; ſo finely ſerrate at the tip as hardly to be obſerved. The umbels are ſo confounded with the lateral umbellets, that the primary one is diſtinguiſhed with difficulty: the petals and involucres are yellow. The primary flowers are male and five-petalled; the reſt hermaphrodite and four-petalled; the petals are tranſverſely oval. Capſules warted, with very fine white hairs ſcattered over them. There are barren branches from the lower axils of the leaves.

Native of Siberia[b].—It flowers from may to auguſt. Cultivated in 1758, by Mr. Miller[e].]

82. Root perennial. Stems many, ſucculent, three feet high, covered with a purple bark. Leaves oblong, ſmooth, ſhaped like thoſe of the Willow, dark green. The upper part of the ſtalks divide, and in the fork is ſituated an umbel of flowers of a greeniſh yellow colour; appearing in june: the ſeeds ripen in auguſt. It was diſcovered in the Levant by Tournefort, who ſent the ſeeds to the royal garden at Paris.

[Cultivated in 1739, by Mr. Miller[e].

83. Root annual. Stem upright, from a foot to two or three feet high, ſmooth. Leaves alternate, remote, ſmooth, finely ſerrate, with a very few villoſe hairs along the keel: the lower ones ſubpetioled, broader towards the end; the upper ones emarginate at the baſe, and above the baſe bent down at the ſides. Involucre lanceolate. Involucels cordate. Both finely ſerrate. Petals entire, ſuborbiculate, yellow. Germs obſcurely warted. A trifid umbellet grows from the axils of the leaves. The upper part of the plant is greeniſh yellow[f].—Native of England, France, Germany, Switzerland, Auſtria Carniola, Piedmont; in corn-fields. With us it has been found at Black Notley in Eſſex, by Mr. Ray. Between Harefield common and Battle's-well, by Mr. Blackſtone. Near Northfleet, by Mr. Hudſon. N. ſide of Everſden-wood Cambridgeſhire, by Mr. Relham. At Ripton in Huntingdonſhire by Mr. Woodward. In the iſle of Wight by Dr. Stokes.

Dillenius ſuppoſed Ray's *Tithymalus ſegetum longifolius* to be the ſame with this; and Mr. Hudſon has put it down as a variety. He obſerves that the leaves are very minutely ſerrate at the baſe only, in the variety. Mr. Woodward remarks that the leaves of the *platyphyllos* are nearly entire at the baſe. See n. 50, and 72.

84. Native of New Zealand[b].

85. Perennial. Stem a foot, eighteen inches, or two feet in height, upright, round, ſmooth, ſea-green, much branched, leafy. Leaves broader than in *E. Cypariſſias* (n. 75.), ſea-green, ſmooth, linear-lanceolate, ſeſſile, acuminate, quite entire. Umbel of eight or more rays, leaves of the involucre as many: the lateral umbels dichotomous. Involucels cordate. All the flowers fertile, according to Linneus; but Scopoli affirms that thoſe on the firſt diviſions are male. Petals four, yelloWiſh, obſcurely horned. Capſules ſmooth, ſomewhat warted on the prominent parts. The milk is very acrid[b].

Native of France, Holland, Germany, Switzerland, Carniola, Savoy. Found in Scotland by Mr. Mackay 1792. It flowers in july.

Cultivated here in 1570[b].

86. Leaves quite entire, glaucous underneath, but not villoſe. The lateral umbels ſo crowded together at the top of the ſtalk, as hardly to be diſtinguiſhed from the primary one. The rays half a foot long, angular, twice biſid. Involucels quite entire, two-leaved, of the ſame breadth and length. Flowers between the branches barren and deciduous; the reſt fertile and peduncled. Petals four, red. Capſule without warts or hairs, but ſomewhat wrinkled on the back of each lobe[c]. Native of Iſtria, Verona and Piedmont.

87. Perennial. Stems procumbent, a foot in length. Leaves entire, alternate, glaucous, ſmooth, attenuated at the baſe; the lower ones narrower, widening gradually. Peduncles from the upper axils ſimple, fertile. Involucre broad-lanceolate. Involucels triangular-cordate. Flowers ſeſſile in threes. Petals four, broad, blunt, truncated. Capſules ſmooth[b]. —Native of Provence and Auſtria.

88. This bears a great reſemblance to *E. Eſula* (n. 85.), and in the ſpring the umbels are very much alike: this, however, differs in being larger; in having leaves not all alike, but the upper ones or thoſe of the branches briſtle-ſhaped or linear; the lower, or thoſe of the ſtem lanceolate, the involucre conſiſting of about twenty leaves, which are reflex and broader; the involucels two-leaved, ovate-cordate, yelloWiſh or reddiſh; the petals creſcent-ſhaped, yellow. Capſules ſmooth. Others, however, affirm that they are warted. As the umbel withers, lateral branches with very narrow filiform leaves grow up, reſembling the pine[c].

South of France, Germany, Auſtria, Carniola, Switzerland, Piedmont, on hills, by road ſides, and in dry barren places. Woods at Enville in Staffordſhire.—It flowers with us from may to ſeptember. Parkinſon informs us, that it was oftentimes found in the country gardens of poor folks in many places with us. They knew it by the name of *Welcome to our houſe*; whence we may preſume that it was a favourite plant; probably it was then much in uſe as a purge; the Spurges were alſo then in requeſt, not only for taking away warts, but for curing the leproſy and other cutaneous diſorders.

89. Root perennial. Stems many, a foot long, trailing, with ſcars at bottom from the fallen leaves. Theſe are alternate, ſucculent, concave, ſea-green, ſeſſile; the upper ones reflex. The umbel has from ſeven to nine rays. Involucre of as many ovate, ſharp leaflets, more ſlender than the leaves. Involucels two-leaved, ſubcordate, broader, concave, ſharp, ſomewhat ſcabrous about the edge. Flowers

within the primary and secondary involucels male, the rest hermaphrodite. Calyxes ferrate about the edge. Petals four, yellow, horned with round tips, shining. Capsules smooth [a].

Native of the South of France, Spain, and Italy.—It flowers from april to june. Cultivated in 1570 [b].

90. Root perennial. Stem three, four or five feet high, round, smooth, with branches towards the top, which are alternate, and shorter than the stem. Leaves alternate, sessile, blunt, smooth, glaucous underneath, sometimes quite entire, sometimes very finely serrate. Involucres and involucels ovate; the former of five, six or seven leaves. The primary flowers male, five-petalled, abortive; the secondary hermaphrodite, four-petalled. Calyx very pale yellow. Petals entire, yellow, blunt, not horned. Capsules warted [c].—Native of Sweden, Denmark, Germany, Holland, Switzerland, France, Piedmont.—With us it flowers from may to auguſt: and was cultivated so long since as 1570 [d].]

91. Root perennial. Stems several, a foot or more in height, upright, unbranched, round, smooth, very light green, with red blotches here and there. Leaves frequent, alternate, resembling those of Spurge-Laurel, but less thick and stiff, above smooth and somewhat shining, from glaucous deep green, underneath paler, and covered with a slender scarcely conspicuous woolliness, having hairs only along the nerve: these leaves are all of the same size except the bottom ones, which are smaller and rounder. The number of rays in the umbel is usually five; but sometimes on the middle and stronger stems another ray (or two) branches out, with a leaf or two under each, somewhat bigger than the rest. Of the two flowers on each ray, one only usually comes to maturity. The capsules are not properly wrinkled, but armed with many soft prickles on the middle; for at the corners they are smooth; they do not hang down but stand upright on slender short peduncles. The flower has usually five petals, but sometimes only four.

Mr. Ray relates a case of a boy being killed by a dose of the juice of this plant [e].

Native of Ireland in the mountains of Munster, where it is known by the name of *Makinboy*. It was sent from thence by Stephens, Professor of Botany at Dublin, to the Eltham garden, where it flowered in 1729. It was first mentioned in *Phytologia Britannica*; next in the second edition of the catalogue of the Oxford garden; then by Merret in his Pinax, and by Ray in his first edition of his Catalogue of English plants [a].

It was found by Mr. Doody among the corn near Twickenham park, over against Richmond, and near Otterspool: but no person having met with it there afterwards, Doody is supposed to have mistaken another plant for it. Mr. Hudson, however, sets it down as being found between Feversham and Sittingbourn in Kent.—It flowers in may and june.]

92. This rises with an upright branching stem to the height of four feet. Leaves oblong, pointed, alternate. Flowers in umbels from the forks; they are small and yellow, and rarely produce seeds in England. Native of Italy, Sicily, Candia, &c.

93. [Root perennial. Stem herbaceous, not woody, slightly downy, purple, two or three feet high. The flowering part of it, during flowering, grows to more than twice its original length. Leaves alternate, remote, thin, not leathery and stiff, slightly downy, especially the root-leaves underneath: stem-leaves lanceolate, very entire, broader upwards, both blunt and pointed, tapering down into leaf-stalks: flower-leaves obovate-oblong, and obovate with a short point at the end. Lateral flowering branches numerous, twice bifid, and forming a sort of long spike. Leaves of the involucre five, roundish, obovate. Involuceis circular or elliptic, cloven half way down on each side, and rounded at each extremity, with a small point just perceptible to the naked eye. Petals crescent-shaped, yellow, in decay acquiring a purplish hue, and then sometimes mistaken for *E. Characias* [a]. Vaillant will not have this separated from the next. Common in woods and hedges, in a clayey soil. It flowers in may, sometimes sooner, and continues to july.

94. Stems shrubby, proliferous, thick. Leaves hairy, perennial. Petals crescent-shaped, erose or gnawn, whereas those of the next species are entire [b]. Haller joins these two; this differs, however, in having the involucels entire, subemarginate, orbicular, perfoliate; the germ smooth; the stigmas semibifid, blackish: the anthers yellow roundish; styles greenish yellow; stem unbranched, two feet high, reddish, naked below: leaves obtuse, not acuminate, subpetioled, red often mixed among the green, two or three inches long, and one broad; the younger ones very villose [c].—According to Scopoli, the leaves are very finely serrate at the tip. The flowers between the rays and the branches male and sessile, with most of the stamens imperfect, and five petals. The other flowers fertile and four-petalled. Germ neither villose nor warted.

Native of woods, in the southern countries of Europe.

95. Stems several, shrubby, four feet high, (or even five or six in gardens) simple, thick, somewhat woolly, thickening upwards, reddish, with transverse scars from the fallen leaves. These are closely imbricate, lanceolate, leathery, somewhat downy, and bent back; green, with an elevated rib on each side, towards the flowers becoming broader and blunter. Umbel small, crowded, terminating, sessile; rays short, and numerous branches of the same length from the upper part of the stems. Leaves of the involucre eight, ten, or more, somewhat lanceolate, small bent back. Involucels cloven half way down. Flowers small; those within the first involucels male, the rest perfect. Petals four, purple. Styles scarcely cloven, whereas in the *amygdaloides* they are deeply cloven. Germs villose. The whole plant is very downy [d].

Native of France, Spain, Italy and Germany, in woods and hedges. With us it is rare. At Papermill Pool Dam, in Heywood Park, Staffordshire, where Dr. Plot marks it to grow, Dr. Stokes has searched for it in vain. It has however been found in Needwood forest in great plenty by Mr. Whately. It flowers in june.]

96. This rises with a shrubby purple stem near three feet high. Leaves sessile, alternate. Umbels terminating, and forming a sort of spike. Involucres yellow. Petals black. The flowers appear in may, and the seeds ripen in july.

[97. Stem round, naked, jointed. Leaves narrow-linear, two inches long, ending in a small point. Petals entire. Capsules seem to be smooth.—Native of the island of S. Croix, and communicated by Vahl [e].]

98. Root almost simple, a span in length, going straight down, a little writhed. Stems diffused in a ring, roundish, jointed; joints knotty; dichotomous, slightly hairy. Leaves at the knots opposite, on short petioles, obovate, the upper ones oblanceolate, naked. Flowers heaped at the ends of the branches, males mixed with hermaphrodites, the petals of a beautiful rose-colour. Capsules smooth.—Native of the East-Indies, in driving sand. Communicated by König [f].]

PROPAGATION AND CULTURE.

1—25. The plants of the two first divisions of this vast genus are in general known by the name of *Euphorbium*. (The others were mostly known among authors, before Linneus, by the name of Tithymalus, or Spurge.) These plants are preferred in many curious gardens, more for the oddness of their structure, than any real beauty; but being so extremely different in their form, from almost any

plants

plants of European production, many curious perſons have been induced to preſerve the ſeveral ſorts in their gardens.

They are all of them full of a milky acrid juice, which flows out on their being wounded in any part; this juice will bliſter the fleſh, if it happens to lie upon any tender part for a ſhort time, and will burn linen almoſt as bad as aqua fortis, therefore the plants ſhould be handled with great caution; nor ſhould the ends of their branches be ever bruiſed or injured; for if they are, it frequently occaſions their rotting down to the next joint, and ſometimes will deſtroy the whole plant, if thoſe injured branches are not cut off in time; ſo that whenever the branches appear to have been injured, the ſooner they are cut from the plants, the leſs danger there will be of their ſuffering from it; nor ſhould any of the branches be cut between the joints for the ſame reaſon.

Moſt of theſe plants were firſt brought to Europe by the Dutch, who have been very curious to introduce great numbers of plants from India, and alſo from the Cape of Good Hope: from the latter a very great variety of curious plants have been of late years brought to Europe, many of which produce very elegant flowers, and are the greateſt ornaments of the conſervatory in the winter and ſpring ſeaſons. Theſe have been brought over in ſeeds, but the different ſorts of Euphorbia came over moſt of them in plants or cuttings; for theſe may be eaſily tranſported to any diſtance, if either of them are put up in boxes, with any ſoft dry package, to prevent their being bruiſed, or their ſpines from wounding each other, and kept from moiſture and cold; with this care they may be kept ſix months out of the ground, and if carefully planted will take root, and thrive as well as if they had been newly taken from the old plants, or out of the ground but a ſhort time; which is a much more expeditious method of obtaining the plants than from ſeeds, when they can be procured.

The greateſt part of theſe ſucculent plants grow naturally upon barren rocky places, or in dry ſandy ſoils, where few other plants will thrive: therefore they ſhould never be planted in rich or loamy earth here, nor ſuffered to receive much wet, which will cauſe them to rot. The beſt mixture of earth for theſe plants is about a fourth part of ſcreened lime-rubbiſh, a fourth part of ſea-ſand, and half of light freſh earth from a common; theſe ſhould be mixed well together, and frequently turned over before the mixture is uſed, that the parts may be incorporated, and the compoſt ſweetened by being expoſed to the air. If this mixture is prepared a year before it is wanted, it will be the better, that it may have the benefit of the winter's froſt and the ſummer's heat to mellow it; and the oftener it is turned over, and the ſmaller the heaps are in which it is laid, the air will penetrate it better, and render it more fit for uſe.

Theſe ſorts are eaſily propagated by cuttings, which ſhould be taken from the old plants in june; theſe muſt be cut at a joint, otherwiſe they will rot. When theſe cuttings are taken off, the milky juice of the old plants will flow out in plenty; therefore there ſhould be ſome dry earth or ſand applied upon the wounded part, which will harden and ſtop the ſap; and the wounded part of the cuttings ſhould alſo be rubbed in ſand or dry earth, for the ſame purpoſe; then the cuttings ſhould be laid in a dry part of the ſtove for ten days or a fortnight; and ſome of thoſe whoſe branches are large and very ſucculent, may lie three weeks or more before they are planted, that their wounds may be healed and hardened, otherwiſe they will rot. When the cuttings are planted, they ſhould be each put into a ſmall halfpenny pot, laying ſtones or rubbiſh in the bottom, and filling the pots with the mixture before directed; then plunge the pots into a moderate hot-bed, and if the weather is very hot, the glaſſes of the hot-bed ſhould be ſhaded in the middle of the day, and the cuttings ſhould be gently watered once or twice a week, according as the earth may dry: in about ſix weeks or two months the cuttings will have put out roots, ſo if the bed is not very warm, the plants may continue there, provided they have free air admitted to them every day, otherwiſe it will be better to remove them into the ſtove, where they may be hardened before the winter; for if they are too much drawn in ſummer, they are very apt to decay in winter, unleſs they are very carefully managed. During the ſummer ſeaſon, theſe plants ſhould be gently watered two or three times a week, according to the warmth of the ſeaſon; but in winter they muſt not be watered oftener than once a week, and it ſhould be given more ſparingly at that ſeaſon, eſpecially if the ſtove is not warm: the firſt ſort will require more warmth in the winter than any of the other, as alſo leſs water at that ſeaſon. This, if well managed, will grow ſeven or eight feet high; but the plants muſt conſtantly remain in the ſtove, giving them a large ſhare of air in warm weather, and in winter the ſtove ſhould be kept in a temperate degree of warmth.

The fourth ſort is at preſent the moſt rare in England; the plants which have been procured from Holland, have been moſt of them deſtroyed by placing them in ſtoves, where, by the heat, they have in one day turned black, and rotted immediately after. This ſort will thrive well if placed in a dry airy glaſs caſe with Ficoides, and other ſucculent plants in the winter, where they may have free air in mild weather, and be protected from froſt; in ſummer the plants may be expoſed in the open air, in a warm ſituation, but ſhould be ſcreened from much wet: with this treatment, the plants will thrive much better than when they are more tenderly nurſed.

The fifth, eleventh, fourteenth ſorts, &c. are alſo pretty hardy, and will live in a good glaſs caſe in winter without fire, provided the froſt is kept entirely out; in ſummer they may be placed abroad in a warm ſituation: as theſe are very ſucculent plants, they ſhould not have too much wet; therefore if the ſummer ſhould prove very moiſt, it will be very proper to place theſe plants under ſome ſhelter, where they may enjoy the free air, and be ſcreened from the rain, otherwiſe by receiving too much wet in ſummer they will rot in winter.

The eleventh ſort will require to be ſupported, otherwiſe the weight of the branches will draw them upon the pots; and, by training the ſtems up to ſtakes, they will grow four or five feet high, and a great number of ſide branches will be produced.

The twenty-fourth and twenty-fifth, with ſeveral in the third diviſion, (viz. 28, 30, 32, 33, 34, 35, 36, 46) are natives of the Eaſt or Weſt Indies; and being annual, the ſeeds muſt be ſown upon a hot-bed in the ſpring, and when the plants are fit to remove, they ſhould be planted ſeparately in ſmall pots filled with light earth, and plunged into the hot-bed again; they muſt afterwards be treated in the ſame manner as other tender annual plants from hot countries.

The fifty-fourth ſort, which is vulgarly called the Caper buſh, will become a weed in gardens where it is allowed to ſcatter its ſeeds, and when once introduced requires no care, but to keep the young plants clean from weeds; this is the caſe with moſt of the European ſorts: ſeveral of which are notorious weeds in gardens and corn fields.

The annual ſorts ſhould have their ſeeds ſown in the autumn; they will come up in the ſpring, and require no farther culture.

The perennial ſorts may be propagated either by ſowing the ſeeds, or parting the roots, or by cuttings.

57, may be increaſed by off-ſets from the main root; theſe may be taken off in autumn, and planted in a ſhady ſituation, where they will thrive beter than in the full ſun.

58, 59, 78, 92, 95, may be propagated by cuttings during any of the ſummer months: they all require protection from froſt in winter.—[78 muſt be

be kept in the hot-houſe, and being ſo eminently beautiful, it is to be lamented that it is yet confined to the moſt choice collections; which is the more remarkable, as it not only may be increaſed by cuttings, but alſo grows readily from ſeeds, both ſent from Jamaica, and produced in England.]

The other perennials may be increaſed by parting the roots, or ſowing the ſeeds in autumn. They are moſt of them hardy enough to endure the greateſt cold of this country, eſpecially if they be planted in a dry ſoil.

90, 91, ſhould have a ſhady ſituation, and a moiſt ſoil.

93, 94, 95, being inhabitants of woods, muſt alſo have a ſhady ſituation. They will come up from ſcattered ſeeds, and may be increaſed by the roots.

70, ſhould have the roots confined in pots, for when planted in the full ground, they creep to a great diſtance.

96, may be propagated by ſeeds, or from cuttings, and will live abroad, if planted in a dry rubbiſhy ſoil and warm ſituation, otherwiſe the plants are frequently killed by ſevere froſt. The young plants raiſed from ſeeds are generally very fruitful; but the old ones, and thoſe raiſed from cuttings, are barren.

   Pubeſcent-viſcid, leaves linear, quite entire, tube of the corolla filiform three times as long as the calyx.

DESCRIPTIONS, *&c.*

1. Root annual. Stem a hand's breadth high, or leſs, ſquare, reddiſh, ſlightly hairy, ſimple, or dividing at bottom into two ſmall branches, not more. Leaves few, thick, hairy, almoſt round, in pairs, very deeply notched, the lower ones having only about three, but the upper ones five or ſix notches. Flowers axillary, and in a ſpike at the end, coming

but in pairs. Corolla purple (ſometimes white[a].) Bractes palmate, ſubhirſute[b].

About Montpellier. Frequent in the hilly paſtures of Italy, ſpreading a purple carpet in ſome places. In Montferrat, the county of Nice, and near Turin: Verona: on Monte Teſtaceco near Rome. In Apulia. Caſtille, particularly near the Eſcurial.

2. Root annual. Stem from two to four inches high, or more, upright, round hoary, purple, for the moſt part branched, in oppoſite pairs. Leaves oppoſite, ſeſſile, obtuſe, convex above, concave beneath, finely ciliate about the edge, ſlightly hirſute on each ſide, above ſomewhat gloſſy. Flowers from the axils of the leaves, on ſhort peduncles, oppoſite, forming a ſpike or raceme at the tops of the branches and ſtem. Calyx angular, pubeſcent; ſegments lanceolate, acuminate, ciliate, nearly equal, dark purple at the ends, and with a few dark purple globular glands ſtrewed on the outſide. Corolla, tube rather crooked, a little hairy white, ſtained with yellow at the mouth: border blueiſh white, with purple ſtreaks; upper lip ſubovate, bifid, the ſegments ending in three teeth, pubeſcent, blunt, upright, white, with three purple lines on each ſide; lower lip larger, all the ſegments emarginate, the middle ſegment largeſt, and having a yellow blotch, the lateral ones marked with three purple lines. Filaments purpliſh, not prominent beyond the upper lip: anthers purple, or brown, bearded underneath, or having a few white hairs on the lower part where they open. Germ bearded, or a little hairy at the top: ſtyle pubeſcent on the upper part: ſtigma fringed, with very minute glands round the edge. Capſule four-cornered at bottom, compreſſed above, ſlightly notched at the end, a little hairy towards the top, and marked with black dots. Seeds oblong or ovate[c], ſmall, four or ſix in each cell, with a white edge, ſtreaked longitudinally with white linear ſtreaks; the interſtices pale ferruginous[d].

Common on heaths and other dry paſtures, eſpecially on a chalky ſoil; flowering from july to ſeptember. It varies much in ſize, and in the colour of the corolla, which varies to quite white and yellow; it is more or leſs branching, and ſometimes wholly unbranched.

It ſeems to have been unnoticed by the ancients. The Arabians mention it under the name of *Adbil*. Matthæus Sylvaticus, a phyſician of Mantua, who lived about the year 1320, recommended this plant in diſorders of the eyes[e]. It is ſtill in uſe, particularly as an ingredient in Britiſh herb tobacco: and Mr. Lightfoot informs us, that the highlanders in Scotland make an infuſion of it in milk, and anoint the patient's eyes with a feather dipped in it. It is, however, neglected by the faculty; and even thought by ſome to be injurious, at leaſt in inflammations of the eyes. It is a weak aſtringent: but there ſeems to be no foundation for the old notion of its being uſeful in diſorders of the eyes.

3. Leaves linear, with one tooth on each ſide. Corolla like the foregoing[f]. Annual. Native of Italy.

4. Root annual. The whole plant commonly browniſh red. Stem upright, ſtiff, very much branched, from ſix inches to a foot or more in height, hiſpid, obtuſely four-cornered: branches oppoſite. Leaves oppoſite, ſeſſile, linear-lanceolate, turning down, thinly toothed, ſlightly hiſpid, veins few, and hirſute underneath. Bractes lanceolate, nearly upright, purpliſh. Flowers in long, leafy ſpikes, pointing one way, nodding a little at top; in pairs or ſingle, on ſhort peduncles. Calyx hairy on the outſide: the teeth equal and ſharp. Corolla duſky red or purple (ſometimes varying to white), hairy: very different in form from the foregoing, the upper lip being compreſſed, and ſcarcely emarginate, the three lobes of the lower lip ſhorter than the upper, equal, truncate, crenulate: all the lobes of the anthers are thorny at the tip, and bearded at the baſe; at the back where the filament is inſerted, are ſeveral ſmall club-ſhaped threads or appendages. Germ hairy, ſurrounded and ſheathed at the baſe by a ſkinny membrane: ſtyle before the flower opens bent in under the upper lip, afterwards longer than the corolla, moſt hairy towards the bottom. Seeds ovate, very white, with a membranaceous margin on one ſide, elegantly latticed, with longitudinal ridges, and ſimilar tranſverſe ſtreaks[g].

Common both in corn-fields and paſtures; eſpecially where it is moiſt: flowering from july to ſeptember.

According to Linnæus, moſt cattle will eat it. With us it appears to be untouched in paſtures. Wherever may be the caſe while it is young, certainly when it is in full vigour, cattle, ſo far from eating it, do not ſeem fond of the graſs even at the diſtance of ſome inches from the plant.

5. This reſembles the foregoing, but is different in having yellow flowers, the upper lip bearded or villoſe within and without, and emarginate; the lower lip concave, trifid; with the ſegments equal. The leaves narrower, ſcarcely linear, hiſpid, hanging down, the lower ones toothletted, the upper ones entire, like thoſe of flax. Stem one, ſeldom more, rough, hard, woody, upright, wand-like, duſky red. Style yellow; ſtigma ſimple; both permanent. Anthers beardleſs. Capſule ſmooth and green at bottom; at top villoſe, blackiſh red. Seeds brown, oblong[h].

According to Gerard (prov. 286. 4.) it differs from the foregoing, in the ſtem being lower, leſs divaricate, and branched; the leaves broader, and more ſcabrous; the flowers yellow, appearing in ſummer.

Native of Switzerland, Savoy, Auſtria, Friuli, Sileſia, the Palatinate, Piedmont, Tuſcany, and the South of France.

6. This is a little ſtiff, narrower, finer, but frequently higher than the common ſort. The leaves are entire. The flowers yellow[i]. Native of France and Italy.

7. This differs from the fifth in having the leaves linear-lanceolate, not ſtrictly linear; the calyxes villoſe and viſcid, not ſmooth; the corollas ſhut, and not ſhorter than the ſtamens. It is alſo to be diſtinguiſhed from E. linifolia[k].

The ſtem, according to Villars, is more firm and leſs branched; the leaves are a little wider than thoſe of the preceding; the calyx is loaded with yellow, viſcid, odoriferous glands; the flowers are yellow.

Gouan obſerves, that it is only three inches high and ſimple, or a foot high and branched, ſmooth or villoſe. All the leaves are broader at the baſe, thence gradually attenuated, and rough with hairs, moſt frequently quite entire, but ſometimes toothed; the lower ones are oppoſite, the reſt alternate, whence the branches themſelves are ſeldom oppoſite. Flowers on a very ſhort peduncle, alternate, each within a ſingle bracte.

Native of Provence, Dauphine, Switzerland, Savoy, Piedmont, and the County of Nice.

8. Native of New Zealand[l].

9. Root annual. Stem upright, ſtiff, round, ſlender, a ſpan high, ſimple, or having two or four oppoſite branches at top, ſhorter than the ſtem; towards the bottom it is leafleſs, and pubeſcent-viſcid, as the whole plant is. Leaves ſeſſile, oppoſite, an inch long, leſs and leſs towards the top of the plant, thickiſh, bluntiſh. Flowers at the top of the ſtem and branches, ſeſſile, alternate, directed the ſame way, yellow, an inch long. Calycine ſegments linear, obtuſe. Upper lip of the corolla oblong, erect: lower longer, flat three-lobed. Filaments the length of the corolla: anthers villoſe,

DESCRIPTIONS, *&c.*

1. Root annual. Stem a hand's breadth high, or leſs, ſquare, reddiſh, ſlightly hairy, ſimple, or dividing at bottom into two ſmall branches, not more. Leaves few, thick, hairy, almoſt round, in pairs, very deeply notched, the lower ones having only about three, but the upper ones five or ſix-notches. Flowers axillary, and in a ſpike at the end, coming

out in pairs. Corolla purple (sometimes white[a].) Bractes palmate, subhirsute[b].

About Montpellier. Frequent in the hilly pastures of Italy, spreading a purple carpet in some places. In Montferrat, the county of Nice, and near Turin: Verona: on Monte Testaceo near Rome. In Apulia. Castille, particularly near the Escurial.

2. Root annual. Stem from two to four inches high, or more, upright, round hoary, purple, for the most part branched, in opposite pairs. Leaves opposite, sessile, obtuse, convex above, concave beneath, finely ciliate about the edge, slightly hirsute on each side, above somewhat glossy. Flowers from the axils of the leaves, on short peduncles, opposite, forming a spike or raceme at the tops of the branches and stem. Calyx angular, pubescent; segments lanceolate, acuminate, ciliate, nearly equal, dark purple at the ends, and with a few dark purple globular glands strewed on the outside. Corolla, tube rather crooked, a little hairy white, stained with yellow at the mouth: border blueish white, with purple streaks; upper lip subovate, bifid, the segments ending in three teeth, pubescent, blunt, upright, white, with three purple lines on each side; lower lip larger, all the segments emarginate, the middle segment largest, and having a yellow blotch, the lateral ones marked with three purple lines. Filaments purplish, not prominent beyond the upper lip: anthers purple, or brown, bearded underneath, or having a few white hairs on the lower part where they open. Germ bearded, or a little hairy at the top: style pubescent on the upper part: stigma fringed, with very minute glands round the edge. Capsule four-cornered at bottom, compressed above, slightly notched at the end, a little hairy towards the top, and marked with black dots. Seeds oblong or ovate[c], small, four or six in each cell, with a white edge, streaked longitudinally with white linear streaks; the interstices pale ferruginous[d].

Common on heaths and other dry pastures, especially on a chalky soil; flowering from july to september. It varies much in size, and in the colour of the corolla, which varies to quite white and yellow; it is more or less branching, and sometimes wholly unbranched.

It seems to have been unnoticed by the ancients. The Arabians mention it under the name of *Adbil*. Matthæus Sylvaticus, a physician of Mantua, who lived about the year 1320, recommended this plant in disorders of the eyes[e]. It is still in use, particularly as an ingredient in British herb tobacco: and Mr. Lightfoot informs us, that the highlanders in Scotland make an infusion of it in milk, and anoint the patient's eyes with a feather dipped in it. It is, however, neglected by the faculty; and even thought by some to be injurious, at least in inflammations of the eyes. It is a weak astringent: but there seems to be no foundation for the old notion of its being useful in disorders of the eyes.

3. Leaves linear, with one tooth on each side. Corolla like the foregoing[f]. Annual. Native of Italy.

4. Root annual. The whole plant commonly brownish red. Stem upright, stiff, very much branched, from six inches to a foot or more in height, hispid, obtusely four-cornered: branches opposite. Leaves opposite, sessile, linear-lanceolate, turning down, thinly toothed, slightly hispid, veins few, and hirsute underneath. Bractes lanceolate, nearly upright, purplish. Flowers in long, leafy spikes, pointing one way, nodding a little at top; in pairs or single, on short peduncles. Calyx hairy on the outside: the teeth equal and sharp. Corolla dusky red or purple (sometimes varying to white), hairy: very different in form from the foregoing, the upper lip being compressed, and scarcely emarginate, the three lobes of the lower lip shorter than the upper, equal, truncate, crenulate: all the lobes of the anthers are thorny at the tip, and bearded at the base; at the back where the filament is inserted, are several small club-shaped threads or appendages. Germ hairy, surrounded and sheathed at the base by a skinny membrane: style before the flower opens bent in under the upper lip, afterwards longer than the corolla, most hairy towards the bottom. Seeds ovate, very white, with a membranaceous margin on one side, elegantly latticed, with longitudinal ridges, and similar transverse streaks[g].

Common both in corn-fields and pastures, especially where it is moist: flowering from july to september.

According to Linnæus, most cattle will eat it. With us it appears to be untouched in pastures. Whatever may be the case while it is young, certainly when it is in full vigour, cattle, so far from eating it, do not seem fond of the grass even at the distance of some inches from the plant.

5. This resembles the foregoing, but is different in having yellow flowers, the upper lip bearded or villose within and without, and emarginate; the lower lip concave, trifid; with the segments equal. The leaves narrower, scarcely linear, hispid, hanging down, the lower ones toothletted, the upper ones entire, like those of flax. Stem one, seldom more, rough, hard, woody, upright, wand-like, dusky red. Style yellow; stigma simple; both permanent. Anthers beardless. Capsule smooth and green at bottom; at top villose, blackish red. Seeds brown, oblong[h].

According to Gerard (prov. 286. 4.) it differs from the foregoing, in the stem being lower, less divaricate, and branched; the leaves broader, and more scabrous; the flowers yellow, appearing in summer.

Native of Switzerland, Savoy, Austria, Friuli, Silesia, the Palatinate, Piedmont, Tuscany, and the South of France.

6. This is a little stiff, narrower, finer, but frequently higher than the common sort. The leaves are entire. The flowers yellow[i]. Native of France and Italy.

7. This differs from the fifth in having the leaves linear-lanceolate, not strictly linear; the calyxes villose and viscid, not smooth; the corollas blue, and not shorter than the stamens. It is also to be distinguished from E. linifolia[k].

The stem, according to Villars, is more firm and less branched; the leaves are a little wider than those of the preceding; the calyx is loaded with yellow, viscid, odoriferous glands; the flowers are yellow.

Gouan observes, that it is only three inches high and simple, or a foot high and branched, smooth or villose. All the leaves are broader at the base, thence gradually attenuated, and rough with hairs, most frequently quite entire, but sometimes toothed; the lower ones are opposite, the rest alternate, whence the branches themselves are seldom opposite. Flowers on a very short peduncle, alternate, each within a single bracte.

Native of Provence, Dauphine, Switzerland, Savoy, Piedmont, and the County of Nice.

8. Native of New Zealand[l].

9. Root annual. Stem upright, stiff, round, slender, a span high, simple, or having two or four opposite branches at top, shorter than the stem; towards the bottom it is leafless, and pubescent-viscid, as the whole plant is. Leaves sessile, opposite, an inch long, less and less towards the top of the plant, thickish, blunt. Flowers at the top of the stem and branches, sessile, alternate, directed the same way, yellow, an inch long. Calycine segments linear, obtuse. Upper lip of the corolla oblong, erect: lower longer, flat three-lobed. Filaments the length of the corolla: anthers villose,

[a] Bauh. prodr. [b] Linn. [c] Curtis, Withering, Hudson, Lightfoot. [d] Gærtner. [e] D'Asso. [f] Linn. syst. [g] Curtis, Withering, Lees, Gærtner. [h] Lightfoot. [i] Villars. [k] Linn. mant. [l] Forster.

be kept in the hot-house, and being so eminently beautiful, it is to be lamented that it is yet confined to the most choice collections; which is the more remarkable, as it not only may be increased by cuttings, but also grows readily from seeds, both sent from Jamaica, and produced in England.]

The other perennials may be increased by parting the roots, or sowing the seeds in autumn. They are most of them hardy enough to endure the greatest cold of this country, especially if they be planted in a dry soil.

90, 91, should have a shady situation, and a moist soil.

93, 94, 95, being inhabitants of woods, must also have a shady situation. They will come up from scattered seeds, and may be increased by the roots.

70, should have the roots confined in pots, for when planted in the full ground, they creep to a great distance.

96, may be propagated by seeds, or from cuttings, and will live abroad, if planted in a dry rubbishy soil and warm situation, otherwise the plants are frequently killed by severe frost. The young plants raised from seeds are generally very fruitful; but the old ones, and those raised from cuttings, are barren.

   Pubescent-viscid, leaves linear, quite entire, tube of the corolla filiform three times as long as the calyx.

DESCRIPTIONS, *&c.*

1. Root annual. Stem a hand's breadth high, or less, square, reddish, slightly hairy, simple, or dividing at bottom into two small branches, not more. Leaves few, thick, hairy, almost round, in pairs, very deeply notched, the lower ones having only about three, but the upper ones five or six-notches. Flowers axillary, and in a spike at the end, coming

out in pairs. Corolla purple (ſometimes white[a].) Bractes palmate, ſubhirſute [b].

About Montpellier. Frequent in the hilly paſtures of Italy, ſpreading a purple carpet in ſome places. In Montferrat, the county of Nice, and near Turin: Verona: on Monte Teſtaceo near Rome. In Apulia. Caſtille, particularly near the Eſcurial.

2. Root annual. Stem from two to four inches high, or more, upright, round hoary, purple, for the moſt part branched, in oppoſite pairs. Leaves oppoſite, ſeſſile, obtuſe, convex above, concave beneath, finely ciliate about the edge, ſlightly hirſute on each ſide, above ſomewhat gloſſy. Flowers from the axils of the leaves, on ſhort peduncles, oppoſite, forming a ſpike or raceme at the tops of the branches and ſtem. Calyx angular, pubeſcent; ſegments lanceolate, acuminate, ciliate, nearly equal, dark purple at the ends, and with a few dark purple globular glands ſtrewed on the outſide. Corolla, tube rather crooked, a little hairy white, ſtained with yellow at the mouth: border blueiſh white, with purple ſtreaks; upper lip ſubovate, bifid, the ſegments ending in three teeth, pubeſcent, blunt, upright, white, with three purple lines on each ſide; lower lip larger, all the ſegments emarginate, the middle ſegment largeſt, and having a yellow blotch, the lateral ones marked with three purple lines. Filaments purpliſh, not prominent beyond the upper lip: anthers purple, or brown, bearded underneath, or having a few white hairs on the lower part where they open. Germ bearded, or a little hairy at the top: ſtyle pubeſcent on the upper part: ſtigma fringed, with very minute glands round the edge. Capſule four-cornered at bottom, compreſſed above, ſlightly notched at the end, a little hairy towards the top, and marked with black dots. Seeds oblong or ovate [c], ſmall, four or ſix in each cell, with a white edge, ſtreaked longitudinally with white linear ſtreaks; the interſtices pale ferruginous [d].

Common on heaths and other dry paſtures, eſpecially on a chalky ſoil; flowering from july to ſeptember. It varies much in ſize, and in the colour of the corolla, which varies to quite white and yellow; it is more or leſs branching, and ſometimes wholly unbranched.

It ſeems to have been unnoticed by the ancients. The Arabians mention it under the name of *Adbil*. Matthæus Sylvaticus, a phyſician of Mantua, who lived about the year 1320, recommended this plant in diſorders of the eyes [e]. It is ſtill in uſe, particularly as an ingredient in Britiſh herb tobacco: and Mr. Lightfoot informs us, that the highlanders in Scotland make an infuſion of it in milk, and anoint the patient's eyes with a feather dipped in it. It is, however, neglected by the faculty; and even thought by ſome to be injurious, at leaſt in inflammations of the eyes. It is a weak aſtringent: but there ſeems to be no foundation for the old notion of its being uſeful in diſorders of the eyes.

3. Leaves linear, with one tooth on each ſide. Corolla like the foregoing [f]. Annual. Native of Italy.

4. Root annual. The whole plant commonly browniſh red. Stem upright, ſtiff, very much branched, from ſix inches to a foot or more in height, hiſpid, obtuſely four-cornered: branches oppoſite. Leaves oppoſite, ſeſſile, linear-lanceolate, turning down, thinly toothed, ſlightly hiſpid, veins few, and hirſute underneath. Bractes lanceolate, nearly upright, purpliſh. Flowers in long, leafy ſpikes, pointing one way, nodding a little at top; in pairs or ſingle, on ſhort peduncles. Calyx hairy on the outſide: the teeth equal and ſharp. Corolla duſky red or purple (ſometimes varying to white), hairy: very different in form from the foregoing, the upper lip being compreſſed, and ſcarcely emarginate, the three lobes of the lower lip ſhorter than the upper, equal, truncate, crenulate: all the lobes of the anthers are thorny at the tip, and bearded at the baſe; at the back where the filament is inſerted, are ſeveral ſmall club-ſhaped threads or appendages. Germ hairy, ſurrounded and ſheathed at the baſe by a ſkinny membrane: ſtyle before the flower opens bent in under the upper lip, afterwards longer than the corolla, moſt hairy towards the bottom. Seeds ovate, very white, with a membranaceous margin on one ſide, elegantly latticed, with longitudinal ridges, and ſimilar tranſverſe ſtreaks [g].

Common both in corn-fields and paſtures; eſpecially where it is moiſt: flowering from july to ſeptember.

According to Linnæus, moſt cattle will eat it. With us it appears to be untouched in paſtures. Wherever may be the caſe while it is young, certainly when it is in full vigour, cattle, ſo far from eating it, do not ſeem fond of the graſs even at the diſtance of ſome inches from the plant.

5. This reſembles the foregoing, but is different in having yellow flowers, the upper lip bearded or villoſe within and without, and emarginate; the lower lip concave, trifid; with the ſegments equal. The leaves narrower, ſcarcely linear, hiſpid, hanging down, the lower ones toothleted, the upper ones entire, like thoſe of flax. Stem one, ſeldom more, rough, hard, woody, upright, wand-like, duſky red. Style yellow; ſtigma ſimple; both permanent. Anthers beardleſs. Capſule ſmooth and green at bottom; at top villoſe, blackiſh red. Seeds brown, oblong [h].

According to Gerard (prov. 286. 4.) it differs from the foregoing, in the ſtem being lower, leſs divaricate, and branched; the leaves broader, and more ſcabrous; the flowers yellow, appearing in ſummer.

Native of Switzerland, Savoy, Auſtria, Friuli, Sileſia, the Palatinate, Piedmont, Tuſcany, and the South of France.

6. This is a little ſtiff, narrower, finer, but frequently higher than the common ſort. The leaves are entire. The flowers yellow [i]. Native of France and Italy.

7. This differs from the fifth in having the leaves linear-lanceolate, not ſtrictly linear; the calyxes villoſe and viſcid, not ſmooth; the corollas ſhut, and not ſhorter than the ſtamens. It is alſo to be diſtinguiſhed from E. ſiniſolia [k].

The ſtem, according to Villars, is more firm and leſs branched; the leaves are a little wider than thoſe of the preceding; the calyx is loaded with yellow, viſcid, odoriferous glands; the flowers are yellow.

Gouan obſerves, that it is only three inches high and ſimple, or a foot high and branched, ſmooth or villoſe. All the leaves are broader at the baſe, thence gradually attenuated, and rough with hairs, moſt frequently quite entire, but ſometimes toothed; the lower ones are oppoſite, the reſt alternate, whence the branches themſelves are ſeldom oppoſite. Flowers on a very ſhort peduncle, alternate, each within a ſingle bracte.

Native of Provence, Dauphine, Switzerland, Savoy, Piedmont, and the County of Nice.

8. Native of New Zealand [l].

9. Root annual. Stem upright, ſtiff, round, ſlender, a ſpan high, ſimple, or having two or four oppoſite branches at top, ſhorter than the ſtem; towards the bottom it is leafleſs, and pubeſcent-viſcid, as the whole plant is. Leaves ſeſſile, oppoſite, an inch long, leſs and leſs towards the top of the plant, thickiſh, blunt iſh. Flowers at the top of the ſtem and branches, ſeſſile, alternate, directed the ſame way, yellow, an inch long. Calycine ſegments linear, obtuſe. Upper lip of the corolla oblong, erect: lower longer, flat three-lobed. Filaments the length of the corolla: anthers villoſe,

[a] Bauh. prodr. [b] Linn.

[e] D'Aſſo. [f] Linn. ſyſt.
[g] Curtis, Withering, Leers, Gærtner. [h] Krocker.
[i] Villars. [k] Linn. mant. [l] Forſter.

bifid, the segments divaricate, mucronate. Capsule half the length of the calyx, resembling that of the common sort. It is distinguished by the length of the corolla, with a filiform tube twice or three times as long as the calyx*.

According to Cavanilles, the stem is a foot high, of a dark red colour; the branches decussated and four-cornered. Leaves longer than the internodes, as it were imbricate, studded with very minute glutinous globules. Flowers axillary, in spikes. Calyx cut half way. Tube of the corolla half an inch long; lower lip broader, with rounded segments. Filaments short, fastened to the upper part of the tube, within the upper lip; anthers ovate, twin, two-awned at the base, and perforated. Style red, the length of the corolla: stigma club-shaped. Seeds longitudinally streaked.

Native of Spain. Found there by Barrelier; by Barnades in 1756; by Buens near Espexa, by Cavanilles near Rivas, and by Vahl in Arragon. It flowers there in september.

PROPAGATION AND CULTURE.

These are all annual plants, to be propagated only from seeds, sowed soon after they are ripe, or in the spring, in the borders of the garden. The second sort will not grow in a garden, unless it has grass or some other herbs to protect it. This and the fourth are common weeds. The other sorts are natives of the southern countries of Europe, and are not without difficulty preserved in gardens. The herb-women supply the markets plentifully with the second sort from the pastures.

DESCRIPTION, &c.

All parts of the plant are smooth. Stem shrubby. Branches and twigs alternate, lax, from upright bent in, ash-coloured. Leaves on the twigs alternate, frequent, petioled, elliptic or oblong, drawn to a point at both ends, serrate, a little turned back at the edge, entire at the base, very smooth, thickish, ever-green, in two rows, upright, with an emarginate point, nerved, the upper surface green, but underneath yellowish, an inch or more in length. Petioles decurrent, semicylindric, grooved above, smooth, a line in length. Flowers axillary, in pairs, pedunculed, drooping, seldom either single or in threes. Peduncles filiform, one-flowered, scarcely longer than the petioles. It flowers in september and october. Native of Japan*.

EURYANDRA. (*From* ευρυς *wide, and* ανηρ *male; the filaments or male organ of the plant being dilated, especially at the tip.*)

Leaves on very ſhort petioles oblong three-nerved dotted, ſtamens protruded.

10. Exacum viſcoſum.
Smith ic. rar. 18.
Gentiana viſcoſa. *Ait hort. kew.* 1. 327.
Leaves oblong nerved embracing, flowers five-cleft, braſtles heart ſhaped, perfoliate, longer than the calyx.

DESCRIPTIONS, *&c.*

This genus differs from Gentiana, according to the obſervation of Vahl, in little elſe beſides the number of ſtamens. Dr. Smith however remarks, that it differs from Gentiana in not having a cloven ſtyle; from Swertia in the want of honey-bearing pores; from Chlora in not having a four cleft ſtigma; as well as in the number of the parts being widely different; from Liſianthus in not having its ſtigma formed of two flat plates; and from Chironia in its ſtraight not ſpirally twiſted anthers. Probably many plants referred by Linneus to the laſt genus may belong to this. The eſſential characters of the genus Exacum are, 1. a ſalver-ſhaped corolla; 2. a ſimple ſtyle, with a capitate ſtigma, ſlightly cloven; 3. ſtraight anthers, burſting longitudinally on their inſide [a].

Although theſe plants are removed from the fifth claſs to the fourth, yet ſome of the ſpecies have five parts in the fructification.

The flowers are axillary, or dichotomouſly corymbed and terminating, one-flowered in the diviſions [b].

1. Root annual. Stem a hand's breadth high, dichotomous, herbaceous, four-ſided, ſmooth, faſtigiate. Leaves heart-ſhaped, ſomewhat ſtem-claſping, oleraceous, ſmooth, decurrent at the edge. Corolla ſalver-ſhaped, white; tube cylindric, longer than the calyx; border the length of the tube. Filaments very ſhort. Anthers oblong. Stigmas two, thickiſh. Capſule ſuperior, cylindric. It has the appearance of Gentiana Centaurium.

Native of the Cape of Good Hope; where it was obſerved by Sparrmann [c].

2. Root annual. Stem upright, a palm in height, four-cornered with acute angles, branched, very ſmooth, as is the whole plant: branches few, ſimple, oppoſite, ſhorter than the ſtem. Leaves oppoſite, ſeſſile, an inch long, ſharp at both ends, quite entire, even. Peduncles from the top of the ſtem and branches, ſolitary, one-flowered, ſhort. Calyx four-parted, four-cornered; the parts ovate, acuminate, membranaceous at the edge. Corolla ſubcampanulate, violet-coloured, larger than in the other ſorts, permanent: tube the length of the calyx: ſegments of the border lanceolate, obtuſe. Anthers linear, a little ſhorter than the border. Style the length of the corolla: ſtigma thickened. Capſule globular, even, the ſize of black Pepper.—It has the habit of Chironia trinervis; but differs in ſize, in having a four-cleft corolla, and four ſtamens. It differs widely from E. albens, with which the younger Linneus has joined it, in his ſupplement [d].

Native of the Eaſt Indies.

3. Root annual. Stem a hand's breadth high, dichotomous, ſlightly four-cornered, ſmooth, brachiate. Leaves oppoſite, heart-ſhaped, the upper and lower lanceolate. Peduncles from the diviſions, one-flowered, the length of the flower. Calyx five-leaved. Corolla yellow, ſalver-ſhaped, four-cleft; ſegments lanceolate, ſharp. Filaments briſtle-form; anthers oblong. Germ ovate; ſtyle the length of the ſtamens; ſtigma thickiſh. Capſule cylindric, obtuſe, half two-celled, bivalve. It has the appearance of Gentiana Centaurium.

Native of the Cape of Good Hope [e].

4. Stem erect, a ſpan high, four-cornered, even, ſimple, dichotomous at top. Leaves oppoſite, ovate, ſeſſile, quite entire. Flowers from the diviſions of the ſtem, ſolitary, ſeſſile, larger than the leaves.

Native of the Eaſt Indies [f].

5. Plant like *Chironia trinervis*, but the flower blue. *Root* annual. *Stem* herbaceous, dichotomous, a ſhort ſpan in height. *Leaves* ſeſſile, cordate, veinleſs, ſmooth, ſharp. *Flowers* axillary at the forks, on one-flowered, ſhort peduncles. *Calyx* five-leaved, five-cornered: leaflets half-cordate, membranaceous with a boat-ſhaped keel, oblique, ſtreaked. *Corolla* yellow, ſalver-ſhaped: tube cylindric, longer than the calyx; border five-parted, obovate. *Filaments* ſhort, in the throat of the corolla: *anthers* oblong. *Style* the length of the ſtamens: *ſtigma* thickiſh, oblong, cloven. *Capſule* oblong.—This has alſo the appearance of Gentiana Centaurium.

Native of the Cape [g].

6. The plant is often ſcarcely a finger's height, with a ſtem either quite ſimple or very little branched, and quite ſmooth, upright and ſharply four-cornered. Leaves oppoſite, attenuated, the lower ones ſhorter and ſharp. Peduncles terminating or from the upper axils, ſolitary, one-flowered, very ſhort, angular. Calyx reſembling that of Gentiana Exacoides, four-leaved, four-cornered, with the angles prominent and membranaceous: leaflets ovate, much attenuated, without oblique ſtreaks ſuch as thoſe in E. ſeſſile.

Native of Cayenne.

7. Stem herbaceous, two feet high, erect, quite ſimple except that ſometimes there are two flowering branches from the laſt axils, obſcurely four-cornered without decurrent lines, ſmooth, as is alſo the whole plant, very ſmooth. Leaves oppoſite, ſeſſile, remote, two inches and more in length, very even, ſimply and obſcurely veined, attenuated, quite entire. Spike terminating, erect, pyramidal, almoſt a ſpan long, with abundance of flowers. Bracte awl-ſhaped, very narrow, at the baſe of each calyx; which is tubular, deeply four-cleft; the clefts lanceolate, much attenuated, the ſame length with the tube of the corolla. Corolla twice the length of the calyx, with a cylindrical tube: border before it is unfolded four-cornered, attenuated, rolled up ſpirally at the top: diviſions lanceolate, the length of the tube. Filaments fixed to the middle of the tube, the length of the corolla, dilated at the baſe, with the margins ſubconverging at top. Anthers ſagittate. Germ ſuperior, oblong, acute. Style the length of the ſtamens. Stigma bilamellate. Capſule oblong, one-celled, two-valved. The flowers have the very ſame habit with the other ſpecies, nor do they ſeem to have any character different from this genus, (except in having the ſtigma formed of two flat plates, as in Liſianthus.) The lower part of the ſtamens is falſely repreſented as diſtinct from the filaments in Aublet's figure. There is no nectary, except we regard the arch formed by the upper converging margins of the filament as ſuch.

Native of Cayenne.

8. The whole plant is ſmooth. Stem erect, ſlightly four-cornered by four very ſlender decurrent lines: branches oppoſite, ſimple. Leaves ſeſſile, oppoſite, an inch long and more, narrower and ſhorter than in the preceeding, attenuated to both ends, quite entire, obſcurely veined underneath; the floral leaves narrower, the lower ones longer than the calyx, gradually decreaſing towards the top of the plant,

[a] Smith ic. rar. [b] Joſſieu gen. [c] Linn. ſuppl. [d] Vahl. [e] Linn. ſuppl. [f] Linn. syſt. [g] Linn. ſupp.

the

the uppermoſt ſmall ſcarcely equal to the pedicel. Flowers diſtant, on very ſhort pedicels, with two briſtle-ſhaped, appreſſed bractes at the baſe of the calyx: which is one-leafed, oblong, four-cleft; the clefts lanceolate, attenuated, membranaceous at the edge. Segments of the corolla ovate, acute.

Native of Guiana[1].

9. This is larger than the other ſpecies. Leaves as in Hypericum, glandular, dotted. Corolla blueiſh. Stamens yellow.

Native of the Eaſt Indies, where it was obſerved by König[1].

10. Root perennial. Stem ſomewhat ſhrubby, erect, roundiſh: branches oppoſite, erect, ſlightly quadrangular, green, leafy, many-flowered. Leaves oppoſite, acute, entire, with three or five nerves, reticulated with veins, green on both ſides, ſmooth, dilated into a heart-like ſhape at the baſe. Panicles terminating, erect, ſubdivided in a three-fold order, much branched, many-flowered. Pedicels roundiſh, ſlender, ſingle-flowered. Bractes two at each diviſion of the panicle as well as under each flower, formed like the leaves, but ſmaller, nerved, permanent. Flowers of an elegant golden colour, inodorous, ſlightly drooping, the ſize of thoſe of Chlora perfoliata. Calyx one-third the length of the bractes, bell-ſhaped, deeply five-cleft, viſcid; ſegments erect, blunt, ſomewhat membranous at the edge, ſmooth. Tube of the corolla twice as long as the calyx, tranſparent, highly viſcid, ſwelling at the baſe, and becoming ovate where it is filled by the increaſing germ, contracted at the orifice; ſegments ſpreading the length of the tube, obovate, obtuſe, paler beneath. Stamens five, projecting, half as long as the border: filaments inſerted into the orifice of the tube, leaning towards the upper ſide of the flower, equal, whitiſh, ſlightly incurved at the tip. Anthers oblong, incumbent, cloven at the baſe, burſting by two longitudinal openings on the inſide, permanent, never becoming ſpirally twiſted, pale yellow. Germ oval, with two furrows, green, ſmooth, half as long as the tube. Style ſcarcely ſo long as the ſtamens, declining, round, whitiſh, curved upwards at the end. Stigma capitated, ſlightly cloven[1].

Found by Mr. Francis Maſſon in the Canary iſlands, and introduced in 1781[1].

1. Excoecaria Agallocha.

Lin. ſpec. 1451. *ſuſt.* 882. *Reich.* 4. 238. *Gærtn. fruct.* 2. 126.

Arbor excoecans. *Rumph. amb.* 2. 237. *t.* 79, 80.

2. Excoecaria cochinchinenſis.

Lour. cochinch. 612.

[1] Vahl. [1] Linn. ſuppl. [1] Smith. [1] Hort. kew.

Leaves two-coloured ſpining, ſcales of the ament many-flowered.

DESCRIPTIONS, *&c.*

1. Capſule ſmall, the ſize of a Juniper berry, ſubglobular, three-grooved, ſmooth, black, three-celled, of a papery ſubſtance, not divided within into three diſtinct grains, but merely opening, when preſſed, by three valves. Seeds one in each cell, ſubglobular, acuminate at top, convex on one ſide, very bluntly angular on the other. Rumphius deſcribes the capſules of the ſize of the Caper, ruſeſcent when ripe, and burſting elaſtically; the ſeeds hard, and variegated like thoſe of Ricinus[*].

Native of Amboina and Tongatabu.

2. This is an arboreous ſhrub, eight feet high; with the ſtem and branches irregular, ſpreading, reclining. Leaves lanceolate, ſlightly ſerrate, petioled, ſome oppoſite others ſcattered, the upper ſurface dark-green, the lower very red, both ſhining. Scales of the ament imbricate, ſubterminating. The female flowers have three, long, awl-ſhaped, reflex ſtigmas. Capſule three-lobed, ſomewhat fleſhy, red, ſmall, three-celled, three valved. Seeds ovate, ſmooth and even.

It poſſeſſes an aſtringent agglutinating quality. The whole plant abounds in a glutinous milky juice, which has not the reputation of deſtroying the ſight. Nor is the Agallochum, even of a baſtard ſort found in it.

Native both of China and Cochinchina, where it is cultivated for the beauty of its red leaves[*].

EXOACANTHA. (*From* ἔξω ἄκανθος, *ſpinis horreo.* ὀξυάκανθα *or* ὀξυάκανθος *is the name of a tree in Dioſcorides.*)

Billardiere ic. ſyr. 1. 10. *t.* 2.

Claſs. 5. 2. Pentandria Digynia.

Nat. order of *Umbellatæ* or *Umbelliferæ.*

GENERIC CHARACTER.

CAL. *Umbel univerſal* manifold, ſpreading, the inner rays gradually ſmaller, the inmoſt very ſhort. *Partial* manifold.

Involucre univerſal with rays uſually twelve, channelled, ſpiny at the end. *Partial* halved, with the middle ray very long, ſimilar to the rays of the involucre.

Perianth proper ſcarcely obſervable.

COR. *univerſal* uniform.

Proper five-petalled. *Petals* inflex-heart-ſhaped, equal.

STAM. *Filaments* five, capillary, longer than the corolla. Anthers roundiſh.

PIST. *Germ* inferior, ovate. *Styles* two, ſhorter, ſtraight. *Stigmas* two, ſimple.

PER. *Fruit* ſubovate, ſtriated, bipartile.

SEEDS two, ovate, convex and ſtriated on one ſide, flat on the other.

OBS. *Allied to* Echinophora, *but with uncalycled flowers, all hermaphrodite, equal petals, and naked ſeeds.*

ESSENTIAL CHARACTER.

Involucels ſpiny. *Involucels* halved with unequal rays. *Flowers* all hermaphrodite, with equal inflex-heart-ſhaped petals. *Seeds* ovate, ſtriated.

SPECIES.

1. Exoacantha heterophylla.

Billard. ſyr. 10. *t.* 2.

Leaves pinnate, root-leaflets ovate toothed gaſhed, ſtem-leaves lanceolate acute.

DESCRIPTION, *&c.*

Root ſimple, thickiſh, biennial. Stem two feet high or more, ſtriated, ſubflexuoſe ſmooth. Leaves ſmooth. Stem-leaves uſually entire, with the middle leaflet very long. The two umbels have about forty rays: thoſe of the umbellule nearly equal. Leaflets of the involucel from nine to eleven, unequal: the central ones with ſhort briſtle-ſhaped rays: the circumference with three middle rays, ſometimes five, channelled, ſpiny at the tip. Petals white. Anthers yellowiſh. Fruit ten-ſtreaked.

Found by Billardiere near Nazareth[*].

EYEBRIGHT. See *Euphraſia.*

DESCRIPTIONS, *&c.*

Theſe are ſmall trees or rather ſhrubs, ſome prickly, others not. The leaves are alternate, ſimple or ternate, more frequently unequally pinnate with the common petiole edged; they are thin and have pellucid dots. The flowers are faſcicled or ſubracemed from the axils. The fruit is one-capſuled in the Linnean ſpecies; in the others two-capſuled, but in their habit very like the former; in *F. pentandra* of Aublet from three to five-capſuled, five-petalled, with three bractes under a five-toothed calyx; in *F. Euodia* four-capſuled, with all the parts of fructification in fours; in *F. octandra* one-capſuled, two-valved, containing one ſeed; this has four petals, eight ſtamens, one ſtyle, and a ſimple ſtigma. It abounds in a balſam, as in Burſera, eſpecially in the fruit. Doubtful whether this be of the ſame genus, though the leaves are conformable[a].

1. Forſter made a new genus of this ſpecies, under the title of *Euodia*, from its fine ſmell. But it has no diſtinct marks, except that the ſtigma is four-cleft, whereas in Fagara it is two-cleft, and that it has four capſules, whereas Fagara has but one[b].

Native of the Friendly Iſles, and the New Hebrides[c].

2. This is a native of the iſland of Dominique[d].

3. A ſhrub with wrinkled branches. Leaves alternate, pinnate, with three pairs of leaflets, and the common petiole margined and jointed. Leaflets obovate, quite entire, emarginate, ſmooth. Spikes axillary, ſeſſile, in pairs[e].

According to Browne, it riſes by a branched and ſomewhat prickly ſtalk frequently to the height of eight or ten feet; the wood is very hard, and the branches are abundantly furniſhed with little leaves and ſmall white flowers that riſe on double ſpikes from the axils of the ribs. This ſhrub is very common in the lower lands of Jamaica.] Dr. Houſtoun found it at Campeachy.

Mr. Miller ſays it riſes upwards of twenty feet high, and that from the dried ſpecimens which he received he is convinced there are ſome of the trees which bear male flowers.

It has a goatiſh ſmell[f]. Mr. Miller cultivated it in 1768. It flowers in auguſt and ſeptember[g].

4. Stem ſhrubby, ſcarcely a fathom in height. Branches round, prickly, purple. Prickles ſcattered, horizontal. Leaves many, from the ends of the twigs, unequally pinnate, with about ſix pairs of leaflets; theſe are alternate and oppoſite, ſubſeſſile, ovate, emarginate, ſmooth, half an inch in length. Flowers among the leaves, terminating, panicled, ſmall, white. Capſule wrinkled, one-celled, containing one ſmooth, black ſeed[h].

According to Loureiro, the leaves have only two or three pairs of leaflets, which are acuminate, ſhining, odoriferous, and ſpiny at the back; the flowers have red mixed with the white, and are in racemes on long peduncles.

Gærtner deſcribes the capſule as ſmall, almoſt globular, ſimple or double, coriaceous, ſcabrous on the outſide with callous dots; having within a folded elaſtic plate the conſiſtence of paper, either one or two-celled, and two valved. It has one globular ſeed in each cell fixed to the gaping ſuture in the middle; ſlightly acuminate and compreſſed at top, and having a ſmall navel on the inſide in the middle, almoſt of a bony conſiſtence. In the Japoneſe

[a] Juſſieu. [b] Linn. ſuppl. [c] Forſter. [d] Swartz.
[e] Linn. amœn. [f] Linn. ſyſt. [g] Hort. kew.
[h] Thunberg.

fruit the capſules are uſually ſimple, but in thoſe from China they are more frequently double.

Loureiro ſays that the capſule is four-lobed, and four-celled, and that the ſeeds are peduncled, protruded, black and ſhining.

The bark, leaves and fruit, being aromatic, are frequently uſed in ſoups, inſtead of ſpice. The bruiſed leaves made into a cataplaſm with meal of rice are laid upon the parts afflicted with rheumatiſm, and on bubo[es].

The root, which is woody, with a corky, yellow bark, and a ſharp ſubaromatic flavour, is warm, diaphoretic eminenagogue, and is much eſteemed in intermittent fever, rheumatiſm, *&c.*[b]

Native of China, Cochinchina, and Japan. Introduced in 1773, by Sir James Cockburn, Bart. It flowers in ſeptember[c].

5. This is a ſmall upright tree, ſmooth in all its parts. Branches alternate, ſtriated, flexuoſe, upright, from aſh-coloured purpliſh, elongated, almoſt ſimple. Spines ſcattered, rigid, purpliſh, ſpreading, an inch long, armed with alternate, ſpreading, ſmaller ſpinules. Leaves from the buds ſeveral, pinnate: pinnas oppoſite, ſubſeſſile, in many pairs (about ſeven), obtuſe, very finely notched.

Native of Japan, where it is called *Sai katſi*[a].

6. A ſhrub branching, almoſt erect, five feet in height. Prickles in pairs, ſubulate, recurved, ſtrong, ſubaxillary, brown, ſhining; there is one ſimilar but ſmaller, on the back of each joint of the leaves. Theſe are alternate, ſeſſile, pinnate-jointed: leaflets oblong, attenuated at the baſe, obtuſe, quite entire, ſhining, ſeſſile: joints uſually ſix, in every reſpect ſimilar to the leaflets. Flowers ſmall, axillary, aggregate.

Native of Domingo; flowering in february[a].

7. The trunk of this tree is the ſize of the human leg, ſometimes beſet with many ſhort prickles. It riſes twenty feet high, and its branches are inclined towards the ground. The wood is white, ſolid and odoriferous, with a pretty large pith. Leaves at the ends of the branches, conſiſting of two, three or more pairs of leaflets, without any odd one, oppoſite, at half an inch diſtance, ſmooth, dark green, an inch long, and three quarters of an inch broad in the middle. Flowers white, ſmall, like thoſe of Elder, three-petalled. Fruit round, the ſize of black Pepper. Seed black, ſmelling ſomewhat like Bay berries. The ſmoke of the wood in burning is odoriferous, and probably was the fine ſcent which Columbus found near the ſouth ſhore of Cuba, on his diſcovery of that iſland.

Native of Jamaica and other iſlands of the Weſt Indies[a].

8, 9. Natives of Jamaica[f].

10. An inelegant tree, frequently more than twenty feet in height, abounding in a balſamic glutinous juice, much like that of Burſeria in its qualities. The wood is very white and light. The natives of ſome of the Weſt India iſlands make ſaddles with it of one piece, they have no pad, and only a ſheep-ſkin thrown over them, when they ride. Branches thick, few, long, irregular. Leaves pinnate, tomentoſe on both ſides, winged, deciduous, coming out from the ends of the ſmaller branches with the flowers, or a little after them: leaflets on each ſide four beſides the odd one, ovate, obtuſe, crenate, veined ſcarcely an inch in length. Racemes many, ſimple, an inch or an inch and half long. Flowers very ſmall, with white calyxes, and yellowiſh corollas: moſt of them have a very ſmall germ immerſed in the receptacle, with a double obtuſe ſtigma, and no ſtyle; theſe I have obſerved to be abortive. Fruits green, the ſize of Peas, when broken, the valves diſtil drops of balſam. Seed blackiſh in the naked, whitiſh in the covered part; but the pulp, with which it is cloſely ſurrounded, is ſcarlet.

Native of Curaçao and the adjacent iſlands, flowering in july and auguſt.—Jacquin, from whom the above is taken, named it Elaphrium, from the lightneſs of the wood (ἐλαφρία).

PROPAGATION AND CULTURE.

Theſe are tender plants, and muſt be kept conſtantly in the bark ſtove. They may be increaſed by ſeeds, and alſo by cuttings properly managed.

FAGARA. See *Zanthoxylum*.

FAGONIA. (*So named by Tournefort, in honour of Monſ. Fagon, Archiater to Louis XIV. and a great patron of botany.*)

   Lin. ſpec. 553. *Reich.* 2. 276. *Tourneſ. inſt.* 265.
   Without thorns.

DESCRIPTIONS, &c.

[Theſe are herbaceous plants with a woody baſe. The leaves are either ſimple or ternate: the ſtipules in the two firſt ſpecies become thorns. The flowers are ſolitary and axillary[a].]

1. This is a low plant, ſpreading its branches cloſe to the ground, a foot or more every way.

[Stem four-parted, ſpreading, a foot high, channelled on the upper ſide, knotted and knee-jointed, (five-cornered, dichotomous, *ſyſt.*) Leaves oppoſite, petioled, ternate. Petioled ſubmarginate, the length of the leaflets; which are equal, ſeſſile, linear-lanceolate, mucronate, quite entire, (ſomewhat fleſhy, *ſyſt.*) Stipules four, awl-ſhaped, ſpreading, becoming ſpines, ſhort, bowed back. Peduncles lateral, axillary, ſolitary, one-flowered, alternate, erect, the length of the petiole, from the ſame axil with the branchlet. Petals violet-coloured or blue, ſpreading between the ſinuſes of the calyx with the very claws ſtanding out above it. Capſule nodding, ovate-pyramidal, with the five corners compreſſed and ſubciliate[a]; the cells compreſſed boat-ſhaped, opening at the keel. Receptacle columnar, five-cornered-ſubulate, placed in the axis of the fruit; the valves and ſetaceous umbilical chords are inſerted into this, a little above the baſe. Seeds ovate, narrowing upwards; at bottom, where the umbilical chord is inſerted, ſlightly emarginate; ſo compreſſed as to be almoſt like a leaf, ferruginous-brown, with very minute hollow dots[a].

[a] Thunberg. [b] Loureiro. [c] Hort. kew. [d] Thunberg. [e] Jacquin. [f] Sloane. [g] Swartz.

[a] Juſſieu. [b] Linn. mant. [c] Gærtner.

It

It has the ſtructure of the herb as in *Tribulus*, the flower of *Malpighia*, and is allied to *Zygophyllum*.]

Native of the iſland of Candia. It flowers in july and auguſt, but unleſs the ſeaſon proves warm, the ſeeds do not ripen in England.

[Cultivated in 1739, by Mr. Miller[t].]

2. This is a low plant with a ſhrubby ſtalk, from which come out ſeveral weak branches armed with long thorns; the leaves are thick, narrow, and convex on their under ſide; the flowers come out as in the firſt ſort. [Petals not inſerted into the calyx, nor cordate, but inſerted into the receptacle; violet-coloured, oblong, emarginate. Leaflets linear, acute, flat, thickiſh, ſomewhat villoſe. Spines verticilled, in fours, longer than the leaves. Filaments not appendiculed at the baſe[t].] It was diſcovered by Dr. Shaw in Arabia.

3. This differs from the firſt in being ſmooth, the branches having no thorns; it will alſo live two years, whereas that is annual. It is a native of Spain.

PROPAGATION AND CULTURE.

Sow the ſeeds upon a warm border of freſh light earth in autumn, where they are deſigned to remain, for they do not bear tranſplanting well; in froſty weather ſhelter the plants with mats, or ſome other covering; thin them out to the diſtance of ten inches or a foot, and keep them clean from weeds. Or rather ſow them in pots, and place them under a frame in winter; the following ſpring ſhake them out of the pots, and plant them in a warm border: thus they will flower early, and ripe ſeeds may be obtained.

The ſecond and third ſorts ſeldom flower the firſt year: theſe, therefore, muſt be ſheltered like the firſt for two winters.

Leaves ovate, crowded: capſules three-celled, three-valved.

DESCRIPTIONS, *&c.*

1. The Cheſtnut-tree had its name Caſtanea from a town of the name of Καστανις, in Theſſaly, about which this tree grew in great abundance. Theophraſtus calls it Διος βαλανος, and the nuts καρυα Ευβοικα, and Διος βαλανοι. The Greeks alſo called them Αμυτα and Λοπιμα. It has the ſame appellation in all the European languages. In German *Caſtanienbaum*; in Swediſh and Daniſh *Caſtanietræe*; in French *Chataignier*; in Italian *Caſtagno*; in Spaniſh *Caſtano*; in Portugueze *Caſtanheiro*. In Ruſſian it is *Koſchtan*.]

This tree will grow to a very great ſize, and ſpread its branches finely on every ſide where it has room; but planted cloſely, will ſhoot up ſtraight to a great height. The leaves are large, of a lucid green; [they end in a long very taper point, and the ſerratures terminate in a kind of tender prickle [a]; they are about four or five inches long, and two wide, ſomewhat wrinkled, having ſeveral tranſverſe veins, prominent on the under ſurface, and proceeding from a ſtrong midrib. The aments or catkins of male flowers are pendulous at the ends of the branches, very long, and reſemble thoſe of the walnut [b]. They have a ſtrong ſpermatic ſmell; the flowers are collected in remote little balls, and are ſeſſile. The proportion of male flowers to the females is prodigious. The ſtamens are about nine in number; (five to eighteen. *H.*) In the female flowers the number of ſtyles varies from four to ſeven, but ſix is the moſt common. The calyx becomes an echinate capſule of four valves, of a ſilky ſmoothneſs on the inſide; and containing two nuts, ſometimes three, or only one [c].

The Cheſtnut, in maturity and perfection, ſays Mr. Gilpin, is a noble tree, and grows not unlike the oak. Its ramification is more ſtraggling, but it is eaſy, and its foliage looſe. This is the tree which graces the landſcapes of Salvator Roſa, who painted in the mountains of Calabria, where it flouriſhes.

The Cheſtnut has long been naturalized to the ſouthern countries of Europe. It is ſaid that Tiberius Cæſar firſt brought it from Sardis in Lydia to Italy, whence it was propagated into France, and ſo among us [d]. It is indigenous in many parts of Aſia, in China, Cochinchina, Japan, &c.

The Cheſtnut abounds now in the mountainous parts of Italy, in the South of France, in Switzerland, in the Valais, and many parts of the Alps towards Italy, in Corſica and Sicily, where it grows half way up mount Etna; alſo in Carniola, ſome parts of Germany, &c.]

With us in England, ſays Miller, it was formerly in greater plenty than at preſent, as may be proved by the old buildings in London, which were for the moſt part of this timber; and there are remains of old decayed Cheſtnuts in the woods and chaces not far diſtant from London, particularly Enfield chace. [I doubt very much, however, whether the timber ſuppoſed by Mr. Miller, and by architects in general to be Cheſtnut in our old buildings, be any thing more than Oak of a different grain, and inferior quality.

Mr. Evelyn makes little doubt but that the Cheſtnut is a free-born of this iſland. Dr. Ducarel is of the ſame opinion, and among the ancient records to which he appeals, produces a deed of gift from Henry II. to Flexley abbey, of the tithe of all his Cheſtnuts in the foreſt of Dean. The Hon. Daines Barrington on the contrary (*Philoſ. tranſ. vol.* 61.) thinks that it is not a native. It certainly is not in the woods north of Trent, and though it has been long in the ſouthern parts, yet there is no appearance of its being indigenous [e].

This tree ſeems to be very long lived, and grows to a very great ſize. The famous *Caſtagno de Cento Cavalli* on mount Etna, as meaſured by Mr. Brydone in 1770, is 204 feet in circumference; ſome, however, have doubted whether this be really one tree. Brydone ſays, it had the appearance of five diſtinct trees, but that he was aſſured the ſpace was once filled with ſolid timber, and that there was no bark on the inſide. Kircher, about a century before Brydone, affirms that an entire flock of ſheep might be commodiouſly incloſed within it, as in a fold. *Il Caſtagno del Galea*, of which there is no doubt, meaſured then ſeventy-ſix feet round, at two feet from the ground. But theſe trees grow on a deep rich ſoil, formed from the aſhes of the volcano.

There are ſome fine Cheſtnuts on the banks of the river Tamer in Cornwall, at an old houſe belonging to the Edgecumbe family: and at Beechworth caſtle in Surrey there are not fewer than ſeventy or eighty trees meaſuring from twelve to eighteen or twenty feet in girt.

At Wimley near Hitchin Priory in Hertfordſhire, a Cheſtnut in 1789 girted ſomewhat more than fourteen yards at five feet above the ground; its trunk was hollow, and in part open, but its vegetation was vigorous [f].

In the park adjoining to the garden at Great Canford in Dorſetſhire are four large Cheſtnut trees, one of them meaſuring thirty-ſeven feet round, ſtill bearing fruit plentifully, though much ſhivered and decayed by age [g].

There was an old decayed tree at Fraiting in Eſſex, whoſe very ſtump yielded thirty ſizeable loads of logs. And another in Glouceſterſhire containing within its bowels a pretty wainſcotted room, enlightened with windows, and furniſhed with ſeats, &c [h]. Ben Jonſon, in his poem on Peniſhurſt, makes mention of a Cheſtnut planted at the birth of Sir Philip Sidney.

In Ireland there are or have been many fine Cheſtnuts; as an avenue at Dunganſtown, the eſtate of William Hoey, Eſq., cut down in 1793; one of theſe meaſured fourteen feet three inches, another fifteen feet, and a third ſixteen feet ſix inches round; the length of one was twenty-four feet, and another thirty-ſix.

The moſt remarkable of theſe trees in England is that at Tortworth, the ſeat of Lord Ducie in Glouceſterſhire. Even in the year 1150, ſays Bradley, it was ſtiled the great or old Cheſtnut tree of Tortworth; it fixes the boundary of the manor, and is probably 1000 years old at leaſt. It girted fifty-one feet at ſix feet above the ground, about the year 1720: it divided at the crown into three limbs, one of which then meaſured twenty-eight feet and a half in girt, five feet above the crown. The ſoil in which the tree grows is a ſoft clay ſomewhat loamy, and the ſituation on the N. W. ſide of a hill [i].

Lord Ducie has a beautiful painting of this ancient tree. I have, by the favour of his Lordſhip, an etching of it, made in the year 1772, under which is this inſcription—"The eaſt view of the "ancient Cheſtnut tree at Tortworth, in the County "of Glouceſter, which meaſures nineteen yards in "circumference, and is mentioned by Sir Robert "Atkyns in his hiſtory of that County, as a famous "tree in King John's time, and by Mr. Evelyn in "his Sylva, to have been ſo remarkable for its "magnitude, in the reign of King Stephen, as then "to be called the great Cheſtnut of Tortworth, "from which it may reaſonably be preſumed to "have been ſtanding before the conqueſt."—When this etching was made, it was barely included within the garden wall, which bore hard upon it; but the preſent Lord Ducie removed the incumbrance, and at the ſame time applied freſh earth to the roots, which ſeems to have enlivened it. So late as the year 1788 it produced great quantities of fruit, which though ſmall, were ſweet and well flavoured.

[a] Woodw. MS. [b] Evelyn. [c] Ray. [d] Haller, Scopoli, Ray. [e] Evelyn's Silva by Hunter.

[f] Gilpin's for. ſcen. 1. 59. & 141. [g] M. S. Ord. [h] Groſe's antiquities, ſuppl. vol. 1. [i] Philoſ. account, p. 178. alſo Gent. mag. for 1766. p. 322. where is a figure of it.

Mr. Lyſons alſo has etched two views of this famous tree, from the S. W. and the N. W. He ſays that in 1791 it meaſured forty-four feet four inches round in the thickeſt part, which is much leſs than the dimenſion given by Bradley, and yet this is exceeded by that of Sir Robert Atkyns, who gives it nineteen yards. Sir Robert is of opinion that it was originally ſeveral trees; and Mr. Marſhall thinks it to be two trees grown together. Sir Robert Atkyns mentions a tradition of its having been growing in the reign of King John; and Mr. Peter Collinſon relying on the accounts of Evelyn and Bradley, ſuppoſed it to have been planted in the reign of King Egbert. But Mr. Lyſons ſays, that there does not ſeem to be any authority to ſhow at what period it became remarkable for its ſize, except a very vague tradition; and it could never have been a boundary of the manor, for it ſtands in the centre of it.]

The Cheſtnut is a tree which deſerves our care as much as any of the trees which are propagated in this country, either for uſe or beauty; being one of the beſt ſorts of timber, and affording a goodly ſhade. The leaves continue late in the autumn, turning then to a golden colour; nor are they ſo liable to be eaten by inſects as are thoſe of the Oak, which of late years have frequently happened to the latter, and has rendered them very unſightly great part of ſummer, which I have never obſerved to be the caſe with the Cheſtnut, which renders them more valuable for parks and plantations for ornament; and there is no better food for deer, and many other animals, than their nuts, which moſt of them prefer to acorns; but yet there ſhould not be many of theſe trees planted too near the habitation; becauſe when they are in flower they emit a very diſagreeable odour, which is very offenſive to moſt people.

[The ſhade alſo of the Cheſtnut, like that of the Aſh, is injurious to other plants; it ſhould therefore be planted in thickets, or in detached plantations[a]. Or if theſe trees be planted in large wilderneſs quarters next the walks, or in woods by the ſide of the ridings; and left untrimmed as they ought to be, they will feather to the bottom, and hide the naked and crooked ſtems of other trees[b].

To recommend the reſtoration of this noble and uſeful tree, which has unaccountably been in a manner loſt among us, we muſt obſerve that it] may be cultivated in England ſo as to afford an equal profit with any other ſort of timber tree; ſince the wood is equal in value to the beſt Oak, and for many purpoſes far exceeding it, particularly for caſks, for which it is much uſed in Italy; and for pipes to convey water under ground. In Italy it is planted as coppice wood, to make ſtakes for their vines, which will continue ſeven years.

[It muſt therefore be very proper for ſtakes in eſpaliers and dead hedges, for hop-poles, hurdles, &c. It was formerly uſed for all the ſame purpoſes as Oak, in building, mill-work, and houſehold furniture. And lately ſome of it that was finely variegated has been ſucceſsfully employed in doors and baluſtrades of a ſtair-caſe; a colour being given them, by rubbing them over with alum water, then laying on with a bruſh a decoction of logwood chips, and laſtly a decoction of Brazil wood; they have been frequently taken for mahogany.

Some perſons aſſert that the timber of Cheſtnut is brittle, and decays at heart: whilſt, according to others, it will laſt longer than Oak, is not ſubject to cracks or flaws, and is never attacked by ſpiders or other inſects. Old Cheſtnut is very brittle, and apt to crack, and therefore ſhould never ſtand longer than whilſt it is in a growing ſtate. If cut when it ſquares only ſix inches, it will be as durable as Oak of ſix times its ſize and age; having very little ſap in proportion to other trees. The durability of it when expoſed to the weather is ſufficiently aſcertained, from its uſe for gate-poſts at Wellington in Somerſetſhire, of which the following is an account.—In or about the year 1763, ſome gate-poſts of Oak, and others of Cheſtnut were to be repaired; they had the appearance of being put in at the ſame time, but the latter were much more ſound, inſomuch that ſome of them were adjudged good enough to remain as gate-poſts, and are now to be ſeen there (1788). Such as were too ſmall were taken up, and ſet as poſts to fix rails to. At the ſame time ſome new poſts of Oak were put in, there not being enough of the old Cheſtnut poſts. Though theſe were old when put in, twenty-five years ago, they are now (1788) more ſound than the Oak poſts which were then new. One ſide of the Cheſtnut poſts was the outſide of the tree, but the timber is as ſound there as in any other part; which would not have been the caſe with Oak, the ſap of which, next the bark, ſoon decays. The Cheſtnut gate-poſts had been put down many years before 1745; they have therefore probably ſtood the weather above half a century[c].

Another account ſays, that the branch of a Cheſtnut about thirteen inches ſquare, which in the year 1726 was put down as a hanging poſt for a gate, and carried the gate fifty-two years, when taken up appeared perfectly ſound, and was put down for a clapping poſt in another place.

In 1743 a large barn was built with ſome of this timber, and is now (1792) ſound in every part. About the ſame time ſeveral poſts and rails were put down, which after ſtanding thirty or forty years, generally appeared ſo ſound, as to admit of being ſet up in ſome other place.

In 1772 a fence was made of poſts and rails converted from young Oaks and Cheſtnuts of the ſame age and ſcantling. In 1791 this fence was removed, when the Cheſtnut poſts were found as ſound as when they were firſt put down; but thoſe of Oak were ſo much waſted juſt below the ſurface of the ground, that they could not be uſed again without a ſpur[d].

The nuts are the uſual, and in ſome places almoſt the only food of the common people in the Apennine mountains of Italy, in Savoy, and ſome parts of the South of France; not only boiled and roaſted, but alſo in puddings, cakes and bread. They are eſteemed to be a very flatulent diet, and hard of digeſtion; yet there are inſtances in Italy of men's living to ninety or a hundred years of age, who have fed wholly on Cheſtnuts. They are brought even to faſhionable tables in deſerts. Mr. Ray mentions that they are eaten in Italy with orange or lemon juice and ſugar; and that they are commonly ſold there about the ſtreets, roaſted on a portable furnace; whence we may conclude that this luxury was unknown at London in the laſt century. Theſe nuts are uſed for whitening linen cloth, and for making ſtarch; they are reputed excellent for feeding hogs. The leaves alſo make uſeful litter, and mixed with the dung of the cattle are a good manure[e].

The foregoing account will, I hope, have ſome tendency to encourage the growth of this noble though neglected tree. Mr. Peter Collinſon, who made no doubt of its being a native, aſſigned the great profit ariſing from Cheſtnuts when cut for hop-poles as the reaſon why it is ſo rare to ſee large trees in the woods[f]. Let us hope, however, to ſee it rear its head again as a timber tree among us. An arret of the council at Paris was publiſhed in may 1720, ordering that all the great roads in France ſhould be planted with Cheſtnut or other ſuch fruit or foreſt-trees as are ſuitable to the nature of the ground, at thirty feet diſtance from each other, and within ſix feet of the top of the ditch[g].

The principal plantations which have been made of late years in Great-Britain are in the northern parts of the iſland. The Earl of Fife has planted

[a] Tranſact. ſoc. arts for 1789. p. 10, &c.
[b] Ibid. for 1792. p. 30. [c] Boutcher.
[d] Gent. magaz. [e] M. S. Ord.

[f] Boutcher. [g] Evelyn's ſilva by Hunter.

above 60,000 trees in the county of Murray. George Roſs, Eſq. 4000 in Cromarty. In England Mr. Windham's plantations at Felbrigg in Norfolk, made in 1676, are well known. Mr. Joſeph Mace has planted ſix acres ſeventeen perches, with above 3000 trees, at Aſhford in Biddenden, Kent. John Sneyd, Eſq. 8000 at Belmont in Staffordſhire from 1784 to 1786. Mr. Joſeph Cowliſhaw ſix acres in Carlton foreſt, with above 1800 of theſe trees, mixed with Larch, Aſh, &c. &c.']

Varieties.

There are ſeveral varieties of the Cheſtnut, which have accidentally ariſen from ſeeds; but the difference is chiefly in the ſize of the fruit and leaves. There is, however, one with variegated leaves which is propagated in the nurſeries as a curioſity.

[The ſtriped Cheſtnut is among the moſt beautiful of the variegated trees, the blotches being of a rich ſhining gold colour, ſtrongly marked[t].

The dwarf branching Cheſtnut is no more than a variety of the common ſort.]

2. The Chinquapine or dwarf Virginian Cheſtnut ſeldom grows above twelve or fourteen feet high, but produces great plenty of nuts, which are, for the moſt part, ſingle in each capſule. This tree is very hardy, and will reſiſt the ſevereſt of our winters in the open ground, but is very apt to decay in ſummer, eſpecially in a dry ſoil. But although it delights in moiſture, yet if the wet continues long upon the ground in winter, it frequently deſtroys the trees. It is very common in the woods of America, but is rare in England, [though it was cultivated ſo long ſince as 1699, by the Ducheſs of Beaufort[u].

3. The Beech had its latin name *Fagus* from the Greek φαγος, which in the Doric dialect is put for φαγος, from φαγω, *to eat*, either becauſe mankind lived on beech-maſt before the uſe of corn, or becauſe it was the food of the common people[x]. We are not to ſuppoſe that the *Fagus* of the Romans is the ſame with the φαγος of the Greeks, which is a ſpecies of oak[y]. It is, however, imagined by ſome that the *Fagus* of Cæſar, Virgil and Vitruvius is a ſpecies of Oak, and not the Beech[z]. Our Beech is the Οξυα of the Greeks, and Belon informs us that it is ſtill called by that name on mount Athos.

The appellation is the ſame in all the northern languages, and in all the dialects of the Sclavonian. In German, *Buche*, *Fuke*, or *Boke*; in Daniſh, *Bog*; In Swediſh, *Bok*; in Ruſſian, Poliſh, &c. *Buk*. The French *Hêtre* is from the German *Heſter*, which ſignifies a young Beech. In Italian it is *Faggio*, from the Latin. In Portugueze this is ſoftened into *Foya*; and in Spaniſh into *Haya*; but in ſome provinces it is *Fagos*.

This tree will grow to a very large ſize, lofty and ſpreading, the trunk ſtraight, and covered with a whitiſh bark. The leaves are ſmooth and gloſſy, waved on the edges rather than ſerrate, or ſlightly ſinuate-toothed, three inches and more in length, and two or upwards in breadth; the petioles reddiſh, ſlightly grooved above, four or five lines in length, pubeſcent, as is alſo the midrib of the leaf. Stipules reddiſh-brown, ſhining, lanceolate, conſpicuous. It retains the old leaves through the winter. The male catkins come out in bunches from the ends of the ſmall branches; they are roundiſh, obtuſe, half an inch long, and almoſt as broad; on peduncles from half an inch to fourteen lines in length, pendulous, round, and pubeſcent. Calyx cut half way into ſix ſharp, villoſe, yellowiſh ſegments. Stamens uncertain (4, 6, 8, 9, 11, 12.), from the bottom of the calyx. The female aments come out from the ſame place, a little above the others; they are erect, and on round, whitiſh, villoſe peduncles, four lines or upwards in length: the common involucre has two flowers, is four-cleft, and covered with ſoft ſpines; calyx ſuperior, ſix-leaved, tomentoſe: germ three-celled, with two rudiments of ſeeds in each cell: ſtyles three, (or one three-cleft. *G*); ſtigmas awl-ſhaped, and ſlightly hooked, yellowiſh and ſmooth; at the top of the germ there are alſo ſix whitiſh villoſe ſegments, ſhorter than the ſtyles. The fruit is compoſed of two nuts joined at the baſe, covered with an almoſt globular four valved involucre, with ſoft ſpines on the outſide, but within very ſmooth and ſilky; the nuts when ripe are one-celled and triangular; and contain one or two angular ſeeds[a].

The Beech is native of the greater part of Europe, and the ſouthern provinces of the vaſt Ruſſian empire; but it is not fond of very high or cold ſituations, nor is it found in the northern provinces of Sweden. Mr. Lightfoot doubts whether it be indigenous in Scotland; and Mr. Marſhall thinks it is not a native of the northern counties in England; it proſpers in a chalky and rocky ſoil, but not in light lands. It thrives prodigiouſly in ſheltered bottoms, and of all expoſures moſt diſlikes the weſt. In ſome parts of Hertfordſhire, where the ſoil is a ſtrong clay full of flints, this tree grows to a great ſize, and is extremely beautiful.

Mr. Arthur Young (Travels in France, p. 7.) ſpeaks of a Beech at Chantilly, as the fineſt he ever ſaw; ſtraight as an arrow, and not leſs than eighty or ninety feet high; forty feet to the firſt branch, and four yards in diameter at five feet from the ground.

In Ireland ſeveral fine Beeches are mentioned, though it is not ſuppoſed to be a native of the iſland. As at Tiny-Park, the ſeat of Sir Skeffington Smyth, Bart. three noble trees together, the ſmalleſt fourteen feet round, the next fifteen feet ſix inches at the butt, and fourteen feet eight inches at ſeven feet from the ground, the third is ſixteen feet three inches round, and continues nearly of the ſame girt for thirty-ſix feet.

Cæſar's aſſertion that the *Fagus* was not in Britain when he viſited the iſland, can hardly be got over but by ſuppoſing that his *Fagus* is not the *Beech*.

Beech, ſays the late Mr. White, is one of the moſt grand and lovely of all the foreſt trees, whether we conſider its ſtately trunk, its ſmooth ſilvery rind, its gloſſy foliage, or graceful ſpreading pendulous boughs. No tree, ſays another, is more beautiful when ſtanding ſingly in parks or ornamental grounds, as it throws out its branches very regularly, and feathers almoſt to the ground. In woods or groves it grows clear of branches to a great height[b].

Mr. Gilpin is not inclined to rank the Beech much higher in picturesque beauty than in utility. Its trunk, he allows, is often highly picturesque, being ſtudded with bold knobs and projections, and having ſometimes a ſort of irregular fluting, which is very characteriſtic. The bark, too, wears often a pleaſant hue; it is naturally of a dingy olive, but is overſpread, in patches, with a variety of moſſes and lichens; its ſmoothneſs alſo contraſts agreeably with theſe rougher appendages. This is all the merit Mr. Gilpin allows to the Beech; for we rarely ſee it well ramified; and in full leaf it has the appearance of an overgrown buſh. Virgil, indeed, was right in chooſing the Beech for its ſhade, for no tree forms ſo complete a roof, but its buſhineſs gives it a great heavineſs. The Beech is moſt pleaſing in its juvenile ſtate. A light airy young tree, with its ſpiry branches hanging in eaſy forms, is often beautiful. Some of the fineſt oppoſitions of tint in the autumn ariſe from the union of this tree with the oak[b].]

The Beech is very well adapted to form lofty hedges, to ſurround plantations or large wilderneſs quarters, or for ſcreens where there is not room for trees to extend their branches naturally. Although the timber of this tree is not ſo valuable as that of many others, yet as it grows very faſt in chalky or ſtony ground of little value, with

[t] Tranſact. ſoc. arts. [u] Boutchor. [x] Hort. kew. [y] Voſſius. [z] Ray. [a] Gent. magaz. vol. 54. 658. [b] Pollich, Haller, Gærtner. [b] Woodw. in Wich. [b] Foreſt ſcenery, 43. &c.

a clear

a clear ſmooth bark, and ſtraight trunk; as it will thrive on ſuch ſoils and in ſuch ſituations as better trees will ſcarcely grow in; and as it will reſiſt winds on the declivities of hills better than moſt other trees; the planting of it ſhould be encouraged, eſpecially as it affords an agreeable ſhade, and the leaves both make a fine appearance in ſummer, and continue green as long in autumn as any of the deciduous trees; when they turn brown or orange, and frequently hold on all the winter. In parks, therefore, and other plantations for pleaſure, this tree deſerves to be cultivated among thoſe of the firſt claſs, eſpecially where the ſoil is adapted to it.

[But though the wood of the Beech be brittle, and decays ſoon in the air, yet it will endure long under water, and ſerves for a great variety of uſes, as will appear from the following account. It is of great uſe to turners for making trenchers, diſhes, trays, buckets, &c.; to the joiner for ſtools, bedſteads, and other furniture; to the wheeler and millwright. It makes ſhovels and ſpade-graffs for the huſbandman, and is uſeful to the bellows-maker. Floats for fiſher's nets, inſtead of corks, are made of its bark. It is good for fuel, billet, bavin and coals, though one of the leaſt laſting; and its very ſhavings are good for fining of wine. If the timber lie altogether under water, 'tis little inferior to Elm. Baſkets for ſtrawberries, &c. are made of the bark. Of the thin lamina or ſcale of the wood, ſcabbards for ſwords, band-boxes, hat-caſes, &c. The leaves are uſed abroad, on account of their elaſtic quality, inſtead of ſtraw for the *paillaſſe* to lay under their mattraſſes.—To this enumeration of uſes by Mr. Evelyn, we may add many others.—It is now in much uſe among the cabinet-makers for chairs, both plain and painted, for bedſteads, with the poſts frequently ſtained the colour of mahogany. It is uſed in the country for rafters in building. Much of it is cut out into quarters and planks for various purpoſes; and barn-floors are frequently laid with it. The mill-wright uſes it for cogs, &c. and the wheelwright for ſpokes and fellies. It goes to the dock-yards for wedges, and may be uſed in ſhip's bottoms from the keel to the floor-heads; and to the coal-mines under the name of Newcaſtle railing. Being of an even grain, and without knots, it makes beautiful benches and railing for public rooms, and many ſorts of inſide work in houſes. It is formed into gun-ſtocks, tool-handles, mallets, carpenters planes, &c. heel-pieces, and pegs for heels, and is uſed for the ſounding boards of harpſichords, &c. by the muſical inſtrument-makers. It is cut into pipe-ſtaves for dry goods, eſpecially by the ſoap-caſk coopers, for whoſe uſe a conſiderable quantity is imported in ballaſt from Bremen and Dantzick, in ſlabs and clapboards about five feet in length. It is ſaid that theſe coopers conſumed from twenty to thirty thouſand of theſe clapboards yearly, except in time of war, when the importation is ſtopped. It is excellent fuel, and in burning affords a large quantity of pot-aſh. Much of it is ſent to the Metropolis under the name of London billet, for the uſe of bakers, glaſshouſes, &c. The ſtack-wood, which is made up of the branches, is burnt chiefly into charcoal. The nuts, or maſt, as they are commonly called, fatten ſwine, but the fat is not firm; and they are greedily devoured by mice, ſquirrels and birds; they are ſaid to occaſion giddineſs and head-ach; but when dried and powdered to make wholeſome bread: roaſted, they are ſometimes ſubſtituted for coffee: the poor people in Sileſia uſe the expreſſed oil inſtead of butter. At the beginning of this century Aaron Hill had a project for paying off the national debt with the oil of Beech nuts! but they ſeem to yield little oil in northern countries; in Sweden, Linneus informs us, ſcarcely any can be expreſſed from them.

If the ſoil be tolerably good, Beech will become fit to be felled in twenty-five years. The woods are then drawn, as it is called; that is, the trees fit for fire-wood or billet, poles, timber, &c. are taken down, and no crooked trees are ſuffered to remain. Formerly it was the cuſtom to leave the old ſtools to produce new trees, but as theſe ſeldom grow well and handſome, now during the winter the old ſtools are grubbed up, and the plants which ſpring ſpontaneouſly from the maſt are encouraged to ſupply the places of the trees which are taken down. Once in ſix or ſeven years this operation of drawing the woods may be repeated; and thus there is a conſtant and regular ſucceſſion of trees fit to cut. The price which fire-wood or billet fetches in Buckinghamſhire is near 4d. the foot ſolid meaſure. The poles and better ſtuff for gun-ſtocks, wedges, &c. ſell for 5d. the foot. The largeſt trees for Mill-wrights, &c. ſell at 6d. or 7d. the foot. Stack-wood is 15s. or 16s. the load: and faggots 15s. or 16s. the hundred.

Whatever may have been the caſe with reſpect to our iſland in Cæſar's time, the Beech is now no uncommon tree in many conſiderable tracts of it, particularly on that great ridge of chalk hills which runs from Dorſetſhire, through Wiltſhire, Hampſhire, Surrey, Suſſex, and Kent, branching out into Berkſhire, Buckinghamſhire, and Hertfordſhire. On the declivities of the Cotſwold and Stroudwater hills of Glouceſterſhire, and on the bleak banks of the Wye, in the counties of Hereford and Monmouth. It is indeed to be found in almoſt every county of England.

Some plantations of it have been lately made by the Earl of Fife, in the county of Murray, where his Lordſhip has planted near two hundred thouſand of theſe trees. George Roſs, Eſq. has alſo ſet 13,000 of them in Cromarty. In England, John Sneyd, Eſq. has planted above 14,000 at Belmont in Staffordſhire between the years 1784 and 1786. And the Biſhop of Llandaff 2000 at Ambleſide in the year 1788.]

Varieties.

Some planters ſuppoſe that there are two ſpecies of this tree, the Mountain Beech, and the wild Beech; the firſt of which has a whiter wood than the ſecond; but this difference ariſes only from the ſoil. There are alſo ſeeds of a Beech brought from North America by the name of broad-leaved Beech; but the plants raiſed from them proved to be the common ſort.

[There are two varieties in the nurſeries, one with yellow, and the other with white ſtripes. In Germany they have another variety with dark red leaves, which is called the *Purple Beech*. There are alſo ſome trees in our woods with a rougher bark, which the woodmen call *Hay Beech*.

4. Native of North America, and introduced in 1666 by Meſſrs. Kennedy and Lee[t].

5. This is a ſmall tree about five feet high, with branches aſcending a little. Leaves obſcurely ſerrate, ſmooth, petioled. Male flowers in terminating aments, with a five-cleft calyx and corolla, and twelve ſtamens. Female flowers below on the ſame branch, with a five-cleft calyx, and no corolla. Capſule muricated, three-celled, three-valved, one-ſeeded. The ſeeds are of the ſame form and colour with the common ſort, but very ſmall. The corolla of the male flowers, being very thin and membranaceous, may be conſidered as a nectary. It is doubtful whether this be ſpecifically different from the common Beech. Native of Cochinchina[t].]

PROPAGATION AND CULTURE.

CHESTNUT.

This tree is propagated by planting the nuts in februaty, in beds of freſh undunged earth. The beſt nuts for ſowing are ſuch as are brought from Portugal and Spain, and are commonly ſold in winter for eating, provided they are not kiln-dried, which is generally the caſe with moſt of thoſe brought from abroad, which is done to prevent their ſprouting or ſhooting in their paſſage; therefore, if they cannot be procured freſh from the tree, it will be much better to uſe thoſe of the growth of England, which are full as good to ſow for timber or beauty

[t] Hort. kew. [t] Loureiro.

as any of the foreign nuts, though their fruit is much ſmaller: theſe ſhould be preſerved until the ſeaſon for ſowing, which is the beginning of march, in ſand where mice or other vermin cannot come to them, otherwiſe they will ſoon deſtroy them: before you ſet them, it will be proper to put them into water to try their goodneſs, which is known by their weight; thoſe that ſwim upon the ſurface of the water ſhould be rejected as good for nothing; but ſuch as ſink to the bottom, you may be ſure are good.

In ſetting theſe ſeeds or nuts, the beſt way is, to make a drill with a hoe, as is commonly practiſed in ſetting Kidney Beans, about four inches deep, in which you ſhould place the nuts, at about four or ſix inches diſtance, with their eye uppermoſt; then draw the earth over them with a rake, and make a ſecond drill at about a foot diſtance from the former, proceeding as before, allowing three or four rows in a bed, with an alley between, three feet broad, for a conveniency of clearing the beds, &c. When you have finiſhed your plantation you muſt be careful that it is not deſtroyed by mice or other vermin; which is very often the caſe, if they are not prevented by traps, or other means.

In april theſe nuts will appear above ground; you muſt therefore obſerve to keep them clear from weeds, eſpecially while young: in theſe beds they may remain for two years, when you ſhould remove them into a nurſery, at a wider diſtance. The beſt ſeaſon for tranſplanting theſe trees, is either in october or at the end of february; but october is the beſt ſeaſon; the diſtance theſe ſhould have in the nurſery, is three feet row from row, and one foot or eighteen inches in the rows; you muſt be careful in tranſplanting theſe trees, to take them up without injuring their roots, nor ſhould they remain long out of the ground; but if they have a downright tap-root, it ſhould be cut off, eſpecially if they are intended to be removed again; this will occaſion their putting out lateral roots, and render them leſs ſubject to miſcarry when they are removed for good.

The time generally allowed them in this nurſery is three or four years, according to their growth; but the younger they are tranſplanted, if deſigned for timber, the better they will ſucceed; during which time you ſhould be careful to keep them clear from weeds, obſerving alſo to prune off lateral branches, which would retard their upright growth; and where you find any that are diſpoſed to grow crooked, either by their upper bud being hurt, or from any other accident, you may the year after planting, in march, cut them down to the lowermoſt eye next the ſurface of the ground, which will cauſe them to make one ſtrong upright ſhoot, and may be afterwards trained into good ſtraight trees; but this ſhould not be practiſed unleſs the plants have abſolutely loſt their leading ſhoot; for although the ſtems of the trees ſhould be very crooked, as is generally the caſe when young, yet when they are tranſplanted out, and have room to grow, as they increaſe in bulk, they will grow more upright, and their ſtems will become ſtraight, as I have frequently obſerved where there have been great plantations made of them.

But in doing this, you muſt be careful not to diſturb or break their roots, which, perhaps, might deſtroy them. Theſe trees require no other manure than their own leaves, which ſhould be ſuffered to rot upon the ground; and in the ſpring of the year, the ground ſhould have a ſlight digging, when theſe ſhould be buried between their roots, but not too cloſe to the trees, which might be injurious to their young fibres.

After having remained three or four years in the nurſery, they will be fit for tranſplanting, either in rows to grow for timber, or in quarters for wilderneſs plantations, avenues, clumps, or the orchard, but if you intend them for timber, it is by much the better method to ſow them in furrows, as is practiſed for Oaks, &c. and let them remain unremoved; for theſe trees are apt to have a downright tap-root, which, being hurt by tranſplanting, is often a check to their upright growth, and cauſes them to ſhoot out into lateral branches, as is the caſe with the Oak, Walnut, &c.

But where the fruit of them is more ſought after, then it is certainly the better way to tranſplant them: for as tranſplanting is a check to the luxuriant growth of trees, ſo it is a promoter of their fructification, as may be evinced by obſerving low ſhrubby Oaks, Walnuts, &c. which generally have a greater plenty of fruit than any of the larger and more vigorous trees; and the fruit of ſuch trees is much ſuperior in taſte, though the ſeeds of vigorous trees are vaſtly preferable for plantations of timber; for it is a conſtant obſervation, that, by ſaving ſeeds from dwarf trees or plants, from time to time, they may be rendered much lower in their growth, than is their natural ſize; but where the fruit is moſt deſired, then they ſhould be taken from ſuch trees as produce the largeſt and ſweeteſt nuts, which are commonly found upon ſuch trees as ſpread the moſt, and have horizontal roots: for the weaker trees being leſs capable to furniſh a ſupply of nouriſhment, and having a greater quantity of fruit upon them, to which this muſt be diſtributed, together with their roots lying near the ſurface of the ground, by which means the juices are better prepared by ſun, air, &c. before it enters their veſſels, it is certain their juices are better digeſted, and their fruits better maturated, than thoſe can poſſibly be which grow upon ſtrong vigorous trees, which have long tap-roots running ſeveral feet deep into the earth, and conſequently take in vaſt quantities of crude unprepared juice, which is buoyed up to the extreme parts of the tree; and theſe ſeldom having many lateral branches to digeſt and prepare their juice, by perſpiring and throwing off the crude part before it enters the fruits.

And this, I dare ſay, univerſally holds good in all ſorts of fruit trees, and is often the occaſion of the good and bad qualities of the ſame ſorts of fruits growing on the ſame ſoil.

What has been related about grafting this tree into the Walnut, to promote its bearing, or render the fruit fairer; or inoculating Cherries into the Cheſtnut, for later fruit, is very whimſical and ſilly, ſince neither the Cheſtnut nor Walnut will receive its own kind any other way than by inoculating or inarching; and it is the latter only by which the Walnut can be propagated; nor was it ever known, that any two trees of a different genus would take upon each other ſo as to produce either a good tree or fruit; therefore we may juſtly explode all thoſe different graftings of various trees upon each other, ſo much talked of by the ancients: at leaſt we may ſuppoſe thoſe trees are not known by the ſame names now that they are mentioned by in their writings; for I have made many trials upon them, which, although performed with great care, and in different ſeaſons, yet ſcarcely one of them ſucceeded. But to return:

If you deſign a large plantation of theſe trees for timber, after having two or three times ploughed the ground, the better to deſtroy the roots of weeds, you ſhould make your furrows about ſix feet diſtance from each other, in which you ſhould lay the nuts about ten inches apart, covering them with earth about three inches deep; and when they come up you muſt carefully clear them from weeds: the diſtance allowed between each row is for the uſe of the horſe-hoeing plough, which will diſpatch a great deal of this work in a ſhort time; but it ſhould be performed with great care, ſo as not to injure the young plants, therefore the middle of the ſpaces only ſhould be cleaned with this inſtrument, and a hand-hoe muſt be uſed to clean between the plants in the rows, and alſo on each ſide, where it will be unſafe for the plough to be drawn: and in hand hoeing there muſt be great care taken not to cut the tender rind of the plants. If the following ſpring the ſpaces are carefully ſtirred with the

plough,

plough, it will not only make the ground clean, but alſo looſen it, ſo as that the ſun and moiſture may more eaſily penetrate the ſame, which will greatly promote the growth of the plants; and the oftener theſe ploughings are repeated, the cleaner will be the ground, and the greater will be the progreſs of the plants, which cannot be kept too clean while they are young. When theſe have remained three or four years, (if the nuts ſucceed well) you will have many of theſe trees to remove, which ſhould be done at the ſeaſons before directed, leaving the trees about three feet diſtance in the rows; at which diſtance they may remain for three or four years more, when you ſhould remove every other tree to make room for the remaining, which will reduce the whole plantation to ſix feet ſquare, which will be diſtance enough for them to remain in until they are large enough for poles, when you may cut down every other of theſe trees, making choice of the leaſt promiſing, within a foot of the ground, in order to make ſtools for poles, which in eight or ten years time will be ſtrong enough to lop for hoops, hop-poles, &c. for which purpoſes they are preferable to moſt other trees: ſo that every tenth year here will be a freſh crop, which will pay the rent of the ground, and all other incumbent charges, and, at the ſame time, a full crop of growing timber left upon the ground: but as the large trees increaſe in bulk, their diſtance of twelve feet ſquare will be too ſmall; therefore when they have grown to a ſize for ſmall boards, you ſhould fell every other tree, which will reduce them to twenty-four feet ſquare, which is a proper diſtance for them to remain for good; this will give air to the underwood, which, by this time, would be too much overhung by the cloſeneſs of the large trees; by which means that will be greatly encouraged, and the ſmall timber felled will pay ſufficient intereſt for the money at firſt laid out in planting, &c. with the principal alſo: ſo that all the remaining trees are clear profit, for the underwood ſtill continuing, will pay the rent of the ground, and all other expenſes; and what a fine eſtate here will be for a ſucceeding generation, in about fourſcore years, I leave every one to judge.

[In making a plantation of Cheſtnut trees for the fruit, the ground ſhould have three or four plowings the preceding ſummer and winter; and if one good digging is added a little before planting, it will be a great improvement. Plant your trees in rows ſix feet diſtant every way, dig the ground annually, and when the branches begin to meet, take up every ſecond row, and every ſecond plant, which will leave all the trees at twelve feet diſtance, and the wood of the trees taken up will be very uſeful for many purpoſes. Having dug, or half trenched the land, if it is of a good quality, it may for ſome years be cultivated with potatoes, cabbages, turneps, &c. When the branches beging again to meet, they muſt be reduced as before, and left twenty-four feet aſunder; at which diſtance they may remain. The wood of this laſt felling will ſaw into ſmall boards, and being about twenty years old, muſt be rooted out, for the Cheſtnut ſhoots vigorouſly from ſtools. The remaining trees having produced fruit for ſeveral years, will now bear vaſt quantities, and make great returns of profit.

In raiſing Cheſtnut woods for timber, Mr. Boutcher adviſes for the firſt two years to take a line of beans between the drills: and at the end of two years, early in the ſpring, to remove every ſecond plant in the rows, which will leave them about two and a half feet aſunder, and at this diſtance let them remain three years. Then remove every ſecond row, and every ſecond tree in the remaining rows, which will leave them at the diſtance of eight feet by five. Theſe plants will be uſeful for ſtakes and poles. The ground may now be levelled and dug for any kitchen-garden crops. In February following cut them down, reſerving only the ſtraighteſt and moſt vigorous, at the diſtance of twenty-five or thirty feet. Dwarf crops may be taken between the rows for two years more, after which the trees will ſoon cover the ground.

Both he and Dr. Hunter prefer february to october for tranſplanting. Mr. Marſhall adviſes the nuts to be ſet by the dibble, ſix inches aſunder, in a quincunx order; becauſe drills ſerve as conductors to the field mouſe.

Mr. Hanbury contends for planting a Cheſtnut wood from the nurſery. He adviſes to plant out the trees when they are five feet high, becauſe they will not be ſo large as to require ſtaking, nor ſo ſmall as to be within the reach of hares, rabbets, &c. The diſtance to be two yards, which is far enough aſunder for poles: when they are big enough for this uſe, they ſhould be cut down, leaving a ſufficient number of the moſt thriving trees for timber: this will be in fourteen years: if they are cut within a foot of the ground there will be ſtools for another crop in ten years more. If the plantation is large, the firſt fall of poles may be began ſo early, and the latter deferred ſo late, that the year after the laſt fall the ſtools of the firſt cut poles ſhall have ſent forth others ready for a ſecond cutting. Thus the proprietor will enjoy the benefit of an annual ſale, and the country not be glutted with too great a quantity.

Mr. Hanbury prefers this method, becauſe when the tree is raiſed from the nuts, it is ſubject to a tap-root which ſtrikes beyond the reach of nouriſhment, and conſequently it grows ſlower; and becauſe while they are in the nurſery, a vaſt quantity will ſtand in a ſmall ſpace; whereas when they are raiſed from the nuts, the whole wood muſt be kept clear of weeds till the plants are grown of a ſufficient ſize to defend themſelves.

The Cheſtnut will thrive on almoſt all ſoils, and in all ſituations, if there be no ſtanding water; but beſt in a rich loamy land; it will ſucceed, however, very well on gravel, clay or ſand. All mixed ſoils ſuit it, as well as expoſed places, and the declivities of hills.]

In foreign countries, where the Cheſtnut is cultivated for the fruit, they graft cyons from trees bearing the largeſt and faireſt fruit, upon ſtocks raiſed from the nut. Theſe grafted trees are by the French called Marronders, and are unfit for timber.

The varieties with ſtriped or blotched leaves are maintained by budding, and inarching upon common Cheſtnut, ſtocks.

2. The nuts of the Chinquspine or dwarf Virginian Cheſtnut, ſhould be put up in ſand, in America, as ſoon as they are ripe, and ſent out immediately, otherwiſe they loſe their vegetating quality. When the nuts arrive, they ſhould be put into the ground as ſoon as poſſible, and if the winter ſhould prove ſevere, cover the ground with leaves, tan or peas-haulm, to prevent the froſt from penetrating to the nuts.

Beech.

The Beech-tree is propagated by ſowing the maſt, the ſeaſon for which is any time from october to february; only obſerving to ſecure the ſeeds from vermin when early ſowed: if this be carefully done, the ſooner they are ſown the better, after they are full ripe. [Since Beech-maſt, however, keeps very well, and it is greatly reliſhed by Field-Mice and other vermin, many planters prefer ſpring-ſowing; in which caſe the ſeeds ſhould be ſpread on a mat, in an airy place for a few days to dry, and then put up in bags.]

A ſmall ſpot of ground will be ſufficient for raiſing a great number of theſe trees from ſeed. They muſt be kept clean from weeds; and if they come up very thick, drawing the ſtrongeſt the autumn following: and thus if a ſeed-bed be huſbanded carefully, it will afford a three year's draught of young plants, which ſhould be planted in a nurſery; and, if deſigned for timber trees, at three feet diſtance row from row, and eighteen inches aſunder in the rows. But if they are deſigned for hedges, two feet row from row, and one foot in the rows will be ſufficient. In this nurſery they may remain two

or three years; obſerving to clear them from weeds, and to dig up the ground between the rows, at leaſt once a year; but be careful not to cut or bruiſe the roots, and never to dig the ground in ſummer, when it is hot and dry.

The Beech will proſper on ſtony, barren ſoils; but then the nurſery for the young plants ought to be upon the ſame ſoil: for if they be raiſed in a good ſoil and a warm expoſure, and afterwards are tranſplanted into a bleak barren ſituation, they ſeldom thrive. See NURSERY.

For hedges, the Beech may be kept in a regular figure, if ſheared twice a year, at leaſt when it ſhoots ſtrong: in which caſe, if the hedges are neglected but a ſeaſon or two, it will be difficult to reduce them again.

The varieties with ſtriped leaves may be continued by budding or graffing upon the common Beech: obſerving not to plant them in too good a ſoil, which will frequently cauſe the leaves to become plain.

[The above directions being in ſome reſpects imperfect, I have ſubjoined the following from Mr. Boutcher.

Being provided with maſt from the ſtraighteſt and freſheſt trees in ſeptember, as ſoon as the huſks are quite dry, mix them with ſand, and lay them under an old frame or other covering, to protect them from froſt and wet. The beginning of march ſow them in beds four feet wide, in ſhallow drills eighteen inches aſunder; covering them one inch deep; if the ſeaſon be dry, give them frequent but moderate waterings, from their appearance above ground till the middle of auguſt. In march, next ſeaſon, with a ſpade made very ſharp, undermine the roots, and cut them over between four and five inches under ground. The following autumn or ſpring, either raiſe the whole, or give them another cutting underground, when gently raiſing ſuch as are too thick, leave the remainder at proper diſtances, to ſtand another ſeaſon. Plant ſuch as you have raiſed, after ſmoothing the bruiſed and broken roots, and cutting away ſome of the ſmall hairy fibres, in lines two feet aſunder, and nine or ten inches in the line: here they may remain two, or if the land be poor, three years. Next autumn or ſpring, treat the reſt in like manner. Trim off only croſs ill-placed branches, and thoſe ſparingly. From this nurſery they muſt be removed to another, and planted in rows three feet and a half aſunder, and eighteen inches in the row: here they may remain three years; in poor land four; obſerving always to prune moderately at removal, and to leave abundance of ſmall branches.

Now theſe plants will be fit for common and extenſive plantations: but ſuch as are deſigned for removal when large trees, muſt again be tranſplanted in rows five feet aſunder, and two feet diſtance in the rows, to remain in good ground three, in poor four years. From this remove them again into rows eight feet aſunder, and ſix feet in the row, to remain four years. If required of a ſtill larger ſize, plant them ten feet aſunder every way.

Mr. Young inform us, in his Iriſh tour, that Mr. Mahon made a plantation of all ſorts of foreſt trees in his park, in order to ſee how far the deer would let them eſcape. They devoured every tree except the Beech, not one of which they touched, either leaf, branch, or bark. Many of his Beeches, not more than thirty years growth, were three or four feet in girt, and from thirty to forty feet high.

FENCES. In hotter climates than England, where they have not occaſion for walls to ripen their fruit, their gardens lie open, where they can have water ſence and proſpects; or elſe they bound their gardens with groves, in which are fountains, walks, *&c.* which are much more pleaſing to the ſight than a dead wall: but in colder countries, and in England, we are obliged to have walls to ſhelter and ripen our fruit, although they take away much from the pleaſant proſpect of the garden.

Since therefore we are under a neceſſity to have walls to ſecure our gardens from the injury of winds, as well as for the conveniency of partitions or incloſures, and alſo to ripen our fruit, brick walls are accounted the warmeſt and beſt for this purpoſe: and theſe walls being built pannel-ways, with pillars at equal diſtances, will ſave a great deal of charge, becauſe the walls may be built thinner, than if they were built plain without theſe pannels, for then it would be neceſſary to build them thicker every where: and beſides, theſe pannels make the walls look the handſomer.

Stone walls are by ſome preferred to thoſe of brick, eſpecially thoſe of ſquare hewn ſtones; but where they are deſigned for fruit, they ſhould be faced with brick. Thoſe that are made of rough ſtones, though they are very dry and warm, yet, by reaſon of their unevenneſs, are inconvenient to nail up trees to, except pieces of timber be laid in them here and there to faſten a trellis to them.

But in large gardens it is better to have the proſpect open to the pleaſure-garden, which ſhould be ſurrounded with a foſſe, that from the garden the adjacent country may be viewed, but this muſt depend on the ſituation of the place; for if the proſ-

[a] Linn. ſuppl. [b] Hort. kew.

pect

pect from the garden is not good, it had better be ſhut out from the ſight by a wall, or any other fence, than to be open. As alſo, where a garden lies near a populous town, and the adjoining grounds are open to the inhabitants, if the garden is open, there will be no walking there in good weather, without being expoſed to the view of all paſſengers, which is very diſagreeable.

Where theſe foſſes are made round a garden which is ſituated in a park, they are extremely proper; becauſe hereby the proſpect of the park will be obtained in the garden, which renders theſe gardens much more agreeable than thoſe which are confined.

In the making theſe foſſes there have been many inventions; but, upon the whole, I have not ſeen any which are in all reſpects preferable to thoſe which have an upright wall next the garden; which (where the ſoil will admit of a deep trench) ſhould be ſix or ſeven feet high, ſo as to be above the reach of boys; and from the foot of this wall, the ground on the outſide ſhould riſe with a gradual eaſy ſlope to the diſtance of eighteen or twenty feet; and where it can be allowed, if it ſlopes much farther, it will be eaſier and leſs perceptible as a ditch to the eye, when viewed at a diſtance. But if the ground is naturally wet, ſo as not to admit of a deep foſſe, then, in order to make a fence againſt cattle, if the wall be four feet high, and ſlight poſts of three feet and a half high are placed juſt behind the wall, with a ſmall chain carried on from poſt to poſt, no cattle or deer will ever attempt to jump againſt it, therefore it will be a ſecure fence againſt them; and if theſe are painted of a dark lead colour, they will not be diſcerned at a diſtance: and at the ſame time the chain will ſecure perſons walking in the garden from tumbling over: and if another chain is carried through the poſts at one foot from the ground, it will more effectually prevent cattle from creeping under.

In ſuch places where there are no good proſpects to be obtained from a garden, it is common to make the incloſure of park-paling; which, if well performed, will laſt many years, and has a much better appearance than a wall: and this pale may be hid from the ſight within, by plantations of ſhrubs and Evergreens; or there may be a Quick hedge planted within the pale, which may be trained up, ſo as to be an excellent fence by the time the pales begin to decay.

There are ſome perſons who make ſtockade fences round their gardens to keep out cattle, &c. which, when well made, will anſwer the purpoſe of a fence; but theſe being very expenſive in the making, and not of very long duration, has occaſioned their not being more commonly in uſe.

As to fences round parks, they are generally of paling; which, if well made of winter-fallen Oak, will laſt many years; but a principal thing to be obſerved in making theſe pales, is not to make them too heavy; for when they are ſo, their own weight will cauſe them to decay; therefore the pale ſhould be cleft thin, and the rails ſhould be cut triangular, to prevent the wet lodging upon them; and the poſts ſhould be good, and not placed too far aſunder, burning that part of them which goes into the ground. If theſe things are obſerved, one of theſe pales will laſt, with a little care, upwards of forty years very well. The common way of making theſe fences is, to have every other pale nine or ten inches above the intermediate ones; ſo that the fence may be ſix feet and a half high, which is enough for fallow deer; but where there are red deer, the fence ſhould be one foot higher, otherwiſe they will leap over.

Some incloſe their parks with brick walls; and in countries where ſtone is cheap, the walls are built with this material; ſome with, and others without mortar.

A kitchen-garden, if rightly contrived, will contain walling enough to afford a ſupply of ſuch fruits as require the aſſiſtance of a wall for any family; and this garden being ſituated on one ſide, and quite out of ſight of the houſe, may be ſurrounded with walls, which will ſcreen the kitchen-garden from the ſight of perſons in the pleaſure-garden; and being locked up, the fruit will be much better preſerved than it can be in the public garden: and the having too great a quantity of walling is often the occaſion that ſo many ſcandalous trees are frequently to be ſeen in large gardens, where there is not due care obſerved in their management.

And beſides, the borders of pleaſure-gardens are generally too narrow for the roots of fruit-trees, as will be ſhewn in its proper place, therefore it is in vain to plant them there.

The height of garden-walls ſhould be from ten to twelve feet, which is a moderate proportion; and if the ſoil be good, it may in time be well furniſhed with bearing wood in every part, eſpecially thoſe parts planted with Pears, notwithſtanding the branches being trained horizontally from the bottom of the walls.

I would recommend the White Thorn, the Holly, the Black Thorn and Crab, for outward fences to a good ground, but I do not approve of the intermixing them.

The White Thorn is the beſt quick to plant, becauſe it is the moſt common, and may be clipped ſo as to render it the cloſeſt and hardieſt fence of any other tree; and being very durable, is preferred to all others for outward fences, or for the diviſion of fields, where they are expoſed to cattle, &c.

The Black Thorn and Crab make very good fences, and are to be raiſed as the White Thorn; but if the kernels of Apples or Crabs be ſown, it is beſt to ſow the pommace with them, and they will come up the ſooner, *i. e.* the firſt year, if ſown in the autumn, ſoon after the fruit is ripe.

If Crab-ſtocks be planted while young, in the ſame manner as quick, they make excellent hedges ſoon, and ſo will ſome ſorts of Plums, I mean ſuch as have thorns.

The Black Thorn is not accounted ſo good for fences as the White Thorn, becauſe it is apt to run more into the ground, and is not certain as to the growing, eſpecially if the plants are not ſet very young; but then on the other hand, the buſhes are by much the better, and are alſo more laſting than the White Thorn, or any other, for dead hedges, or to mend gaps; nor are they ſubject to be cropt by cattle, as the others are. The richer the mould is, the better they will proſper, but yet they will grow on the ſame ſort of ſoil that the White Thorn does.

The Holly will make an excellent fence, and is preferable to all the reſt, but is a ſlow grower; but when once it does grow, it makes amends by its height, ſtrength, and thickneſs.

It is raiſed of young ſeedling plants or berries, as the White Thorn is, and the berries will lie as long in the ground before they come up. It delights moſt in ſtrong grounds, but will grow upon the drieſt gravel, amongſt rocks and ſtones.

French Furze will alſo do well upon dry ſandy banks, where few other plants will grow, but they muſt be kept very clean at the bottom, and cut thin, and never ſuffered to grow too high, nor ſhould they be cut in dry weather, or late in autumn, nor early in the ſpring; the doing either of which is ſubject to make it die in patches, which is irrecoverable; nor will it ever break out again from old wood, if cut cloſe in, after it has been ſuffered long to grow out.

Fences may likewiſe be made of Elder; if the ſoil be any thing good, you may put ſticks of Elder, or truncheons ten or twelve feet long, ſlopeways in your banks, ſo as to make a chequer-work; and they will make a fence for a garden the quickeſt of any thing, and be a good ſhelter. But theſe fences are improper for a fine garden, becauſe they ſhoot very irregular, and are ungovernable; as likewiſe the roots of theſe trees ſpread very far, and draw away all the heart of the ground, ſo as to ſtarve whatever

whatever plants grow near them; and add to this the ſcattering of the berries, which will fill the ground near them with young plants; which, if not timely weeded out, will get the better of whatever grows near them: therefore this ſort of fence is ſeldom planted, where a hedge of White Thorn can be had.

Elder planted on a bank, the ſide of which is waſhed with a river or ſtream, will make an extraordinary fence, and will preſerve the bank from being undermined by the water, becauſe it is continually ſending ſuckers from the roots and lower branches, which is of great advantage where the ſtream waſhes away the bank.

For middle fences in a garden, the Yew is the moſt tonſile, governable, and durable plant.

For ſurrounding wilderneſs quarters, Elm, Lime, Hornbeam and Beech, are very proper.

DESCRIPTIONS, *&c.*

1. Root tuberous, roundiſh, compreſſed, in ſhape like that of the Indian Corn-flag, but larger, in the centre of the upper ſide it has a hollow like a navel, whence comes out the ſtalk; the outer ſkin is of a light brown colour, the inſide is white. It lies inactive every other year, and ſometimes will remain two years without putting out either leaves or fibres. Stem a foot and half high, taper and about the thickneſs of a man's little finger. It has lanceolate leaves the whole length, placed alternately, and embracing: the lower leaves are from four to five inches long, and an inch and half broad towards their baſe, ending in obtuſe points; they are a little keel-ſhaped, and of a light-green colour. Flowers axillary, ſolitary, from the upper part of the ſtem, wrapped in a double ſheath, out of which the flower-bud riſes about an inch. The ſheath is compoſed of a double row of keel-ſhaped leaves; the inner row being ſhorter than the outer, and ſituated obliquely to it. The petals are of a pale ſky-blue on the inſide, and of a dirty white on the outſide. The anthers are ſituated below the diviſion of the filaments, and are terminated by ſmall filky hairs.

[This is one of the moſt ſingular and beautiful vegetable productions; and it is much to be regretted that its flowers are of very ſhort duration, opening in the morning, and finally cloſing in the afternoon of the ſame day: a ſtrong plant will, however, throw out many bloſſoms in ſucceſſion. By its ſtructure and œconomy, it approaches very near to the *Siſyrinchium.* It flowers from february to may[a].

Native of the Cape of Good Hope. Cultivated in 1759, by Mr. Miller, to whom it was ſent by Dr. Job Baſter of Zirkzee.—Mr. Curtis's figure was drawn from a plant which flowered in 1791, in the poſſeſſion of R. Forſter, Eſq. of Turnham Green.

Mr. Miller's ſecond ſort (F. enſiformis) may perhaps be no more than a variety of this.] It differs from it in having ſmaller roots, and longer ſword-ſhaped leaves, which have deeper veins; the ſtalk alſo does not divide ſo much, the flowers are ſmaller, and leſs fringed on their borders.

[2. Root bulbous. Scape a ſpan high, one flowered. Leaves ſheathing, one or two; the lower ones longer and narrower. Spathe two-leaved, compreſſed. Corolla bell-ſhaped; the three outer petals larger, ovate, at the tip a little truncate with a minute dagger point; the three inner one-third of the ſize, alternate, haftate, ſubſeſſile, ſpotted. Filaments ſheathing the ſtyle: anthers three, linear, nearly the length of the ſtigmas. Germ pedicelled. Stigmas two-parted, filiform. Capſule linear.

Native of Mexico, where it was obſerved by Mutis[b].]

PROPAGATION AND CULTURE.

They are both propagated by offſets ſent out from the roots, in the ſame way as the Ixia, and ſhould be cultivated in the ſame manner as is directed for that and the African Gladiolus, being too tender to thrive in the open air in England, nor do they ſucceed well in a green-houſe; therefore the beſt method is, to make a border four feet wide, in the front of the green-houſe or ſtoves, covering it with a proper frame and glaſſes, ſo that the plants may enjoy the free air in mild weather, but be protected from froſt. In ſuch a frame, moſt of the African bulbous and tuberous rooted plants may be brought to great perfection.

[FERREOLA. *From Ferrum, iron; on account of the hardneſs of the wood.*)

DESCRIPTION, *&c.*

Trunk irregular, covered with a dark ruſt-coloured bark, dividing into very numerous irregular branches. Leaves alternate, ſhort-petioled, oval, entire, very ſmooth, ſhining, firm, about half or three quarters of an inch long, and half an inch broad.

Among the mountains this grows to a ſmall tree, but in the low countries it is only a ſhrub. It flowers during the hot ſeaſon. The berries, when ripe, are univerſally eaten, and are very well taſted. The wood is dark-coloured, remarkably hard and durable, and where its ſize will admit, is employed for ſuch uſes as require the moſt durable, heavy wood. Native of Coromandel*.

DESCRIPTIONS, *&c.*

Theſe are herbaceous umbelliate plants, ſome of them with large loſty ſtems; the leaves pinnate and ſuperdecompound: ſeveral lateral umbels ſpring from the peduncle of the principal one that terminates the ſtem.]

1. Common Fennel-Giant, if planted in a good ſoil, will grow to a great height, and divide into many branches. The lower leaves ſpread more than two feet every way, and branch out into many diviſions, which are again ſubdivided into many ſmaller; they are of a lucid green, and ſpread near the ground. From the centre of the plant comes out the flower-ſtem, which when the plants are ſtrong, will be near as large as a common broom-ſtick, and ten or twelve feet high, with many joints; there iſſues from it, when cut, a fetid yellowiſh liquor, which will concrete on the ſurface of the wound. This ſtem is terminated by large umbels of yellow flowers, which come out at the end of june or the beginning of july. The ſeeds ripen in ſeptember, and the ſtalk decays ſoon after; when this is dry, it is full of a light pith which eaſily takes fire. The Sicilians uſe it for tinder. Hence the fable of Prometheus. The leaves decay ſoon after the ſeeds are formed; but the roots continue ſeveral years, eſpecially in a dry ſoil, and annually produce flowers and ſeeds.—[Native of Italy, Sicily, the South of France, Greece, *&c.* In Apulia, where it grows in great plenty, it is grateful to the buffaloes, which form the chief part of the ſubſiſtence of many farmers there. When it becomes of a conſiderable ſize they uſe it to make ſtools and bee-hives *.

It was cultivated by Gerarde before 1597; and he informs us that it attained to the height of fourteen or fifteen feet in his garden, growing greater and fairer than in the places whence it came.]

2. The leaves are compoſed of many narrow flat ſegments, of a gray colour, and are divided into

* Symonds in Young's Annals.

many parts. Stem from three to four feet high, terminated by an umbel of yellow flowers, appearing in july, and ſucceeded by oval compreſſed ſeeds, ripening in autumn.

Native of Spain, Italy, and Sicily. Cultivated in 1768, by Mr. Miller[b].

3. Leaves large ſpreading near the root, of a very lucid green, divided and ſubdivided into many parts; leaflets much broader than in the other ſorts, and divided at the end into three unequal ſegments. Stems ſtrong, eight or ten feet high, terminated by large umbels of yellow flowers. [Fruit lenticular-bracted, ecalycled, of a dirty bay colour. Seeds of the ſame form, foliaceous-compreſſed, very ſlightly convex on one ſide, ſurrounded with a narrow rim, flat on the other or ſcarce ſenſibly concave, without ſtreaks or rim[c].

It is a native of Spain and Barbary; and was cultivated in 1683, by Mr. James Sutherland[d].]

4. Height ſeven or eight feet. The leaves branch out on every ſide pretty wide, and the leaflets are broader than thoſe of the other ſorts, except the preceding; but they are longer than thoſe, and of a darker green colour, ending in three points. The umbels are large, and the flowers are yellow.

Native of Sicily.

5. This is of much humbler growth than either of the former; the ſtalks ſeldom riſing much more than three feet high. The lower leaves branch into many diviſions, with fine briſtle-ſhaped leaflets. The umbel of flowers and the ſeeds are ſmall.

Found in the Levant by Tournefort.

6. This has very branching leaves, with angular channelled foot-ſtalks. At every joint are two oppoſite branches; thoſe towards the bottom are nine or ten inches long, and the others diminiſh gradually to the top; theſe ſide-branches ſend out ſmaller ones at each joint in the ſame manner, having very fine leaves on them, like thoſe of Spignel or *Meum*, ſtanding quite round in ſhape of whorls. The flower-ſtalks are three feet high, having a pretty large umbel of yellow flowers at the top: theſe are ſucceeded by oval flat ſeeds, which ripen in the autumn.

Native of the Levant.

7. This is about three feet high. The leaves are much divided, and the leaflets are very narrow and entire. Umbels ſmall, and cloſe to the ſtalks between the leaves at the joints.

[The extreme divaricate ramifications of the leaves ſuſtain acerоſe leaflets uſually in threes. Four umbels come out from each joint of the ſtem: theſe are pedunculed and not ſeſſile. Involucres very ſhort and reflex. Rays of the univerſal umbel to fourteen, of the umbellule to twelve. Petals yellow[e].

Native of Iſtria, Auſtria, and Carniola. Theſe were all cultivated in 1759, by Mr. Miller[f].

8. See Angelica lucida; from which however the ſpecimen in Gronovius's herbarium, now in the poſſeſſion of Sir Joſeph Banks, is very different.

9. The Aſafœtida, as deſcribed by Dr. Hope, is an umbelled plant, three feet high, upright, branched, glaucous, with a yellow flower. Root perennial. Root-leaves ſix, procumbent, three-lobed-ovate, many times pinnate; leaflets gaſhed, ſubacute, ſubdecurrent; common petiole flat above, with a raiſed line running longitudinally through the middle of it. Stem two feet high, roundiſh, annual, ſlightly ſtreaked, having only one pair of imperfect leaves about the middle; branches naked, ſpreading; the three lower ones alternate and ſupported by the concave membranaceous petiole of the imperfect leaf; the four middle ones are in whorls; the uppermoſt from the top of the ſtem, eight in number, the inner ones erect; all theſe ſupport a compound ſeſſile terminating umbel, beſides from three to ſix branchlets placed on the outſide, bearing the compound umbels; in this manner the lower branches ſupport five, ſeldom ſix branchlets, the middle ones three or four, the upper ones one or two. The univerſal umbel has from twenty to thirty rays; the partial from ten to twenty, with ſubſeſſile florets. There is no involucre, either general or partial. The florets of the ſeſſile umbel are fertile, of the pedunculed umbel moſtly abortive. Petals equal, flat, ovate; at firſt ſpreading, then reflex, with the tip aſcending. Filaments awl-ſhaped, longer than the corolla, curved in: anthers roundiſh. Fruit oblong.—Every part of the plant, when wounded, poured out a rich milky juice, reſembling the imported drug in ſmell and taſte, and at times a ſmell like Garlick, ſuch as a faint impregnation of Aſafœtida yields, was perceivable at the diſtance of ſeveral feet.

Though Aſafœtida has been uſed in medicine for many ages, having been introduced by the Arabian phyſicians near a thouſand years ago, yet there was no ſatisfactory account of the plant which yielded it, till Kæmpfer deſcribed and figured it in his Amœnitates Exoticæ, publiſhed in 1712.

Kæmpfer travelled over a great part of Aſia towards the end of the laſt century, and was in Perſia, upon the ſpot where this drug is collected. His plant differs in many reſpects from that which is deſcribed above; but his fidelity having never been impeached, we muſt conclude that this gum, like ſeveral others, is the produce of more than one ſpecies[g].

According to Kæmpfer, the root of the Aſafœtida is perennial, tapering, ponderous, increaſing to the ſize of a man's arm or leg, covered with a blackiſh bark, and near the top beſet with many ſtrong rigid fibres; the internal ſubſtance is white, fleſhy, and abounds with a thick milky juice, yielding an exceſſively ſtrong fetid alliaceous ſmell. Stem ſimple, erect, ſtraight, round, ſmooth, ſtriated, herbaceous, ſix or ſeven inches in circumference at the baſe, and riſing luxuriantly to the height of two or three yards or more. Root-leaves ſix or ſeven, near two feet long, bipinnate, pinnules alternate, ſmooth, variouſly ſinuated, lobed, and ſometimes lanceolate, of a deep green colour and fetid ſmell. Umbels compound, plano-convex, terminating, many-rayed. Seeds oval, flat, foliaceous, reddiſh brown, rough, marked with three longitudinal lines, having the garlick ſmell, and a ſharp bitter taſte.

It varies much from ſoil and ſituation, not only in the form of the leaves, but in the quality of the juice[h].

It is a native of Perſia; and was raiſed from ſeeds, ſent from the mountains of Ghilan, by Dr. Pallas at Peterſburgh. Dr. Guthrie ſent thence two of the roots to Dr. Hope, one of which grew, flowered and ſeeded in the botanic garden at Edinburgh in 1782[i].

Aſafœtida is the concrete juice of the root, and is procured by the peaſants who live in the neighbourhood of the mountains in the provinces of Choraſaan and Laar in Perſia.—When the leaves begin to decay, the oldeſt plants are ſelected, not leſs than four years ſtanding. The earth is partly cleared away, ſo as to expoſe the upper part of the root. The leaves and ſtem are twiſted off, and uſed as a covering to ſcreen it from the ſun. In this ſtate the root is left forty days, when the covering being removed, the top of the root is cut off tranſverſely. It is then ſcreened again for forty-eight hours, when the juice is ſcraped off, and expoſed to the ſun to harden. This done, a ſecond ſection is made, the ſcreen again employed, and the juice obtained a ſecond time as before. Thus the Aſafœtida is eight times repeatedly collected from the ſame root; but after a third ſection, it remains eight days to recover a ſufficient ſtock of juice.

Aſafœtida is well known by its peculiar nauſeous fetid ſmell, the ſtrength of which is the ſureſt teſt of its goodneſs. This odour is extremely volatile, and of courſe the drug loſes much of its efficacy in keeping. It comes in large irregular maſſes, com-

[g] Philoſ. Tranſac. [h] Woodville. [i] Philoſ. Tranſ.

poſed

posed of various shining little lumps or grains, partly whitish, partly brownish or reddish, and partly of a violet hue: those are accounted the best which are clear, of a pale reddish colour, and variegated with many fine white tears. It is a gummy-resin, but has the gum in largest quantity.

It is the most efficacious of the fetid gums; and is commonly used in hysteria, hypochondriasis, some symptoms of dyspepsia, flatulent colics, and most diseases termed nervous: it is thought to be the most powerful remedy we possess for those peculiar convulsive and spasmodic affections which often recur in hysterics. It is recommended as an emmenagogue, anthelminthic, expectorant, antiasthmatic, and anodyne*.]

PROPAGATION AND CULTURE.

All these sorts have roots which will continue several years; these have thick strong fibres, which run deep in the ground, and divide into many smaller, spreading to a considerable distance every way: the stalks are annual, and decay soon after they have perfected their seeds. As these plants spread very wide, so they should have each four or five feet room; nor should they stand near to other plants, for their roots will rob whatever plants grow near them of their nourishment.

They are all propagated by seeds, which should be sown in the autumn; for if they are kept out of the ground till the spring, they frequently fail, and those which succeed remain a year in the ground, so that much time is lost. The seeds may be sown in drills, by which method the ground may be easier kept clean; they must not be nearer than a foot row from row, and the seeds may be scattered two or three inches asunder in the drills; when the plants come up, they must be kept clean from weeds; and where they are too close together, they should be thinned to allow them room to grow, for they will not be strong enough to remove till they have had two years growth; then in the autumn so soon as their leaves decay, the roots should be taken up with great care, so as not to cut or injure the tap or downright root, and then planted in the places where they are designed to remain, for after this transplanting they should not be removed. They delight in a soft, gentle, loamy soil, not too wet, and are very rarely injured by the hardest frost.

FERULA. See *Bubon* and *Peucedanum*.

[FERULAGO. See *Ferula*.

FESCUE-GRASS. See *Festuca*.

FESTUCA. (*The shoot of a tree or herb*, Pliny *and* Columella; *or grass*, Varro. *The Prætor's wand which the lictor laid on the head of a slave when he was made free.* Plautus.—*From* festus, *which is from the old verb* feo.)

Engl. *Fescue grass*. Fr. *Fétuque*.

Lin. gen. n. 88. *Reich.* 94. *Schreb.* 119. *Juss.* 32.

Class. 3. 2. Triandria Digynia.

Nat. order of *Gramina*, *Graminæ* or *Graffes*.

GENERIC CHARACTER.

CAL. *Glume* many-flowered, two valved, upright, containing the floscules in a slender, (oblong, roundish, *fist. nat.*) spikelet: *valves* awl-shaped, acuminate, the lower smallest.

COR. two-valved: *lower valve* largest, of the same form with the calyx, but larger, roundish, acuminate, ending in a dagger-point.

Nectary two-leaved: leaflets ovate-lanceolate, acute, gibbous at the base: or one-leaved, plano-concave, horizontal, emarginate.

STAM. *Filaments*, three, capillary, shorter than the corolla. *Anthers* oblong.

PIST. *Germ* turbinate. *Styles* two, short, reflex. *Stigmas* simple.

PER. none. *Corolla* very closely shut, growing together, and not gaping.

SEED single, slender-oblong, very sharp at both ends, grooved longitudinally.

* Woodville.

ESSENTIAL CHARACTER.

Cal. two-valved. *Spikelet* oblong, roundish, with acuminate glumes.

Spiked, ſpikelets alternate ſeſſile compreſſed awnleſs.

DESCRIPTIONS, &c.

Panicled Graſſes. According to Scopoli, Feſtuca, Bromus, and Triticum are one genus. In Dr. Stokes's opinion the two laſt are ſo, Bromus being only a panicled Triticum: but in Feſtuca, the outer valve of the corolla gradually narrows into the awn, whereas in the others the awn is inſerted below the point of the valve, or the edge of the valve ſwells out into a thin membrane on each ſide the baſe of the awn. In Feſtuca, the awn is an extenſion of the whole valve; in Bromus and Triticum, only of the keel or middle rib, as in Avena[a]. It is to be lamented that this obvious character is not ſo conſtant as to be depended on.

1. F. bromoides differs from *F. myurus* in the panicle's reſembling a ſpike, and the glumes not being ciliate. It is like *F. ovina*, but has broader leaves[b]. Ray obſerves, that the panicle is broader and ſhorter than in *F. myurus*; the ſpikelets are alſo larger and broader; and the culm has three or four joints.

Its height is about half a foot; the culms are inclined; the leaves are thin and ſmooth, the lower part of them quickly drying up; the panicles branch at the baſe, they are compoſed of ſmooth flatted ſpikelets, containing ſix or ſeven flowers; the outer valve of the corolla terminates in a long awn; the calyx has the outer baſe very ſmall, the inner is large and ends in an awn like the corolla[c].

According to Withering our plant is Gramen bromoides panicula heteromalla, &c. *Scheuch.* 290. *t.* 6. *f.* 10. and not, Gr. paniculatum brom. &c. *Scheuch.* 297. *t.* 6. *f.* 14. On the contrary Villars is of opinion that Scheuchzer has repeated the ſame

[a] Stokes in Withering. p. 96. [b] Linn. [c] Villars.

plant

plant five or six times under different names and descriptions, from p. 290 to 293, and in p. 296, 297.

Native of England and France, on walls and in ſandy paſtures: flowering in june and july. Annual.

2. Feſtuca ovina or Sheep's Feſcue, is a ſmall graſs, ſcarcely exceeding ſix inches in height; perennial, flowering in june and july[a]. Floſcules three to ſix in each ſpikelet, generally acuminate or acuminate-awned[b]. Culms ſomewhat angular, with two or three coloured joints. Root-leaves hirſute, ſtem-leaves ſmooth. Lower ſpikelets pedunculed, linear, four-flowered with the rudiment of a fifth; glumes unequal, the larger ovate the ſmaller ſharp[c].

Chiefly on dry ſandy ſoils, and in elevated ſituations; on all our fineſt ſheep-downs common.

This graſs has been much celebrated for feeding ſheep. Linneus affirms that it is their principal food, and that they have no reliſh for hills and heaths that are without it. Gmelin ſays that the Tartars chooſe to fix during the ſummer where there is the greateſt plenty of this graſs, becauſe it affords a moſt wholeſome nouriſhment to all kinds of cattle, but chiefly ſheep. It certainly is a very ſweet feed, as far as it goes, on ſheep downs. Mr. Anderſon does not ſcruple to affirm that it is capable of affording an immenſe quantity of hay, that it promiſes to be one of the beſt graſſes our country produces, and to make a moſt valuable acquiſition to the farmer. This is carrying our prejudices very far indeed, for in its native ſoil, on dry elevated heaths and commons, its foliage is hard and wiry, its produce very triflíng. In ſuch ſituations it is of a purpliſh-brown colour in ſummer. In a rich moiſt ſoil indeed the foliage retains its verdure, and becomes much longer, but being ſtill a ſmall plant, it can never be productive and conſequently cannot have any pretenſions to be conſidered as fit for a hay graſs. Were the Sheep's Feſcue to be ſown in ſuch a ſoil, the graſſes and other plants natural to that ſoil would quickly overpower it; and it is not merely the graſs, but the nature of the ſoil in which it grows, the elevated ſituation, and the dry ſalubrious air that are acceptable to ſheep.

Mr. Curtis, who has combated the vulgar notion of the excellence of this poor wiry graſs for feeding cattle, particularly ſheep, has however found out that it is excellent for the purpoſe of making a fine graſs-plat, requiring little mowing. When it has once got poſſeſſion of the ſoil, it will form ſo thick a turf, as to ſuffer few intruding weeds, and may be kept in order with little trouble. For this purpoſe it muſt be ſown about the middle of auguſt, in an open, but not too dry ſituation, broad-caſt, and that thickly, on ground nicely prepared and levelled[d].

β. In Sweden, and on the mountains of Wales, Yorkſhire, and Weſtmorland.

3. Red Feſcue Graſs is diſtinguiſhed from the foregoing by its greater ſize, its red colour when ripe, and the culm being cylindric only flatted a little on one ſide. The leaves are covered with a ſoft woolline's on the upper ſide barely perceptible to the naked eye. Culms ſmooth, but within the panicle rough: green, but when the ſeeds are ripe, red[e]. It differs from *F. duriuſcula* in having the ſtem-leaves broader and flat, the ſpikelets a little larger, and the panicle looſer: from *F. myurus*, in having the root-leaves briſtle-ſhaped, and very ſhort awns[f].

Culm eight inches high (from two inches to two feet): ſtem-leaves one or two; ſpikelets four, five, or ſix-flowered[g].

According to Monſ. Villars, the ſtiff hard leaves, thoſe of the ſtem like thoſe next the root, fine and of a ſhining green, with the browniſh red ſhining colour of the flowers, diſtinguiſh this from the innumerable varieties of ſome other ſpecies. The glumes of the corolla are ſhining and ſmooth.

[a] Withering. [b] Hudſon. [c] Lyons faſcic. [d] Curtis's practical obſervations. [e] Linn. [f] Pollich. [g] Lyons faſcic.

High heaths and dry paſtures, flowering in july. Perennial.

4. This is probably nothing more than a variety. Haller makes it a variety of *F. ovina*.

Monſ. Villars allows, that it differs little from F. ovina, but that the leaves are of a darker green, the panicles red, and the ſpikelets a little wider than in F. rubra.

He has a ſpecies which he calls F. heterophylla; and ſays it differs from this in having the ſtem-leaves wider, and the root-leaves narrower; the ſpikelets ſmaller not coloured, the culm and awn as long again: —from F. ovina in having higher culms, wider leaves, thinner and greener ſpikelets, and longer awns. He ſays it is very common about Paris, and refers to Haller n. 1438. as a ſynonym.

5. Root perennial, the thickneſs of a gooſe-quill, creepings very far under ground, covered with broad rudiments of leaves. Culm more than a foot and half in height. Leaves involute-filiform. Panicle oblong, with alternate very ſimple branches, pointing one way; ſpikelets alternate, very many, lanceolate, ſix-flowered, acuminate, awnleſs.

Native of Arabia and Paleſtine[a].

6. Root perennial. Culm twelve or eighteen inches in height. Leaves ſmooth. Branches of the panicle alternate, (moſtly in pairs, *Haſſ.*) Spikelets peduncled, linear, compreſſed, ſix-flowered, aſcending[b].

It agrees with the next ſpecies in having filiform, channelled root-leaves, and flat ſtem-leaves, but the glumes of this are ſmooth[c].—This is eaſily diſtinguiſhed from *F. rubra* by having both root and ſtem-leaves briſtle-ſhaped, ſmall ovate ſpikelets with very ſhort awns, and a more contracted panicle: from *F. ovina* by the roundneſs of the culm, and the ſpikelets conſtantly ending in a very ſhort awn[d].—According to Huſſon, it varies with briſtle-form and filiform roughiſh root-leaves; flat and channelled naked ſtem-leaves; with from four to ten flowers in a ſpikelet, which are either ſmooth or pubeſcent. But he makes the next ſpecies to be a variety of this.

In dry paſtures, flowering in june.

It is early and productive; from theſe circumſtances, and its natural place of growth it appears to be a proper graſs for ſheep paſtures. It varies much in ſize and breadth of leaf as well as colour of its panicle, but in all ſituations is very diſtinct from the *ovina*[e]. All theſe graſſes form an admirable paſture for ſheep, and ſeem to flouriſh moſt when they are bit the cloſeſt, but in general they are not productive.

Monſ. Villars has a ſpecies which he calls *F. cinerea*. It reſembles F. ovina in its characters, but the leaves are hard, ſtiff, thick, turned obliquely, but little raiſed, forming a turf of ſome inches in diameter; the panicles are ſomewhat aſh-coloured, but leſs ſo than the leaves, the ſpikelets are almoſt turned to one ſide, and are villoſe; the outer valve of the corolla ends in an awn ſcarcely one third of the length of the valve. It differs from this ſpecies in its villoſe glumes terminated by an awn, whereas in the *duriuſcula* they are ſmooth without any viſible awn.

7. Culms a foot or eighteen inches in height, filiform, cylindric, with two ſwelling knots. Root-leaves a foot long, cylindric, ſcarcely ancipital; ſtem-leaves ſhorter, channelled. Panicle ſmall: ſpikelets ten or twelve oblong, pubeſcent, hoary; the lower ones in pairs pedicelled: the upper ones ſeſſile, ſolitary. Glumes terminating in a minute awn. Bulbs often produced within the ſheaths of the culm. Very nearly allied to F. duriuſcula[f].

In woods and hedges, flowering in june and july.

8. Leaves from a foot to eighteen inches long. Panicle condenſed, from a ſpan to a foot in length: ſpikelets green and purple, cylindric, diſtich: awn the length of the glume[g], but more frequently none.

[a] Linn. ſpec. [b] Lyons faſcic. [c] Linn. [d] Pollich. [e] Curtis. [f] Linnæ [g] Lyons faſcic.

Florets about eight. Calycine glumes unequal, acuminate; of the corolla nearly equal, pointed, the outer a little larger and longer, the inner often bifid [1].

Huds. who joins the *Meadow* with the *Flote-Fescue*, doubts whether this be a distinct species since it has so many things in common with them.—Curtis, though he allows it to be very similar, yet asserts it to be specifically different.

It grows in large tufts, and is conspicuous by the breadth of its leaves, the height of its stems, and the drooping of its panicle at least before it flowers. In very luxuriant spots the leaves are sometimes half an inch wide; but in general this grass varies little except in size, and sometimes in having awns.

It is found in moist meadows, and woods, but most frequently in wet situations, as by river sides and in other grounds; flowering in june and july, and is perennial [2].

Linnæus affirms that it makes very excellent feed, but that it is luxuriant only in a rich soil: but this is spoken of our F. pratensis, which he names elatior in Fl. suec.—Curtis asserts that it grows to a great height in marshes, is hardy and very productive, but too harsh and coarse for hay, yet that it may perhaps be a good grass for soils which cannot be drained of their too great moisture, or which are apt to be overflowed.

9. Culms aggregate, cylindric, a foot or eighteen inches in height. Panicle directed to one side, branched but not diffused, linear and often a span in length, bending a little but not nodding. Spikelets subsessile, linear, with five flosculæ in each, (five to eight, *Leers*): glumes very unequal, awns longer than the spikelets [3]; according to Haller, growing from below the tip.

On walls and in barren places, flowering in june. It is annual, and is called Capon's-tail Grass.—First observed by Mr. Goodyer on the walls of Winchester [4].

10. Root perennial. Culms three feet high, erect, strict, round, striated, very smooth, with one or two purple joints. Leaves involute-setaceous, strict, very smooth, striated, mucronate-pungent, glaucous, widened into a membrane at the base, sheathing, whitish. Stipules intrafoliaceous, very short, or none. Panicle branched, loose, of a golden-bay or bronze colour, with the branches commonly in pairs. Peduncles angular, subflexuose, erect. Spikelets compressed, usually four-flowered, smooth. Calycine valves almost equal, keeled, acuminate not awned, membranaceous and pellucid at the edge, brown at the base. Valves of the corolla longer, acuminate, one larger, keeled, embracing the other. Anthers purplish, included. Styles very short. Seed brown. The panicle is more or less branched.

Linnæus seems to have referred this grass to the genus Anthoxanthum, merely from the habit, and the colour of its flowers; but they are clearly triandrous.

Dr. Smith, whose sagacity and attention in developing this species are eminently conspicuous, informs us that he has learnt from Savoy, that this grass is likely to become of considerable use, and that large quantities of it are now in cultivation [5].

Native of the South of France, Switzerland, *&c.* Found on Mont Cenis by Dr. Smith in 1787, and cultivated from the seeds which he brought over, by Mr. Fairbairn, in the botanic garden at Chelsea, in 1788 [6].

11. Root creeping. Culms two feet high, and upwards, straight, branched at the base. Spike from two inches to a foot or more in length: spikelets remote, two inches long, sharpish, from six to eight-flowered. Leaves glaucous, smooth, convoluted, sharp and rigid at the end. Glumes mucronate. Perennial.—Native of the sandy shores of Provence [7].

[1] Curtis. [2] Curt. lond. [3] Lyons fasc. [4] Ger. emac. [5] Linn. transf. 3. 111. & 2. 101. [6] Id. 2. 112. 114. [7] Linn. mant. and Ger. prov.

12. Culm lofty, branched. Leaves from broadish sheaths, narrow, longitudinally, involute, long, subulate. Panicle subdivided; spikelets upright, an inch in length, obscure, with sixteen to twenty-four flosculæ.—Native of Palæstine [1].

F. fusca of Villars (98. n. 7.) may perhaps be our spadicea.

13. Root perennial. Culms from a foot to eighteen inches in length, (in dry situations not more than a span, according to Krocker) somewhat bulbous at the base, having three knots, lying on the ground, but when in flower ascending obliquely. Root-leaves narrowish, flat, hairy on the upper surface, especially at the base: stem-leaves the same, only shorter; sheaths villose above. Panicle very simple; peduncles alternate, simple, short, one-flowered, the longest longer and on a single branchlet two-flowered. Spikelets five to seven, ovate, somewhat swelling, upright, three, four, and sometimes five-flowered (three, *Lin.*—three to six, *Weber.*—eight, four of which are perfect and four imperfect, *Haller*) coloured (purple or green, *Lyons*). Outer valve of the calyx frequently longer than the spikelet; inner shorter and narrower. Flosculæ hairy at the base; outer valve five-nerved, ciliate about the edge, obtuse at the end and trifid; inner flat, bifid and often trifid at the end. Nectaries two, obtuse. The extreme flosculæ is barren [2]. Allied to the genus Melica [3].

On barren pastures, both dry and wet; frequent on moorish ground. In flowers in july and august.

14. Culm round, streaked, upright, two feet high. Leaves linear streaked, with very fine villose hairs, especially on the sheaths. Panicle ample, and spreading very much: peduncles capillary, flexuose, streaked, scabrous: pedicels less spreading. Calyxes marked with lines, lanceolate, with long awns.

Native of Japan [4].

15. *Root* perennial, striking deep into mud. *Culm* from one to three feet in length (or even much longer in water), creeping at bottom, and sending forth young shoots, afterwards nearly upright; covered with the sheaths of the leaves as far as the panicle. *Leaves* broadish and smooth; those of the young shoots upright, keel-shaped, and shortish; those of the stem longer, flattish, weak, and hanging down, in the winter season lying flat on the water. *Panicle* long (often more than a foot in length) generally bending down a little, sometimes forming a kind of spike, but most commonly branched; the branches sometimes pressed to the culm, sometimes diverging from it. *Spikelets* cylindric, slender, an inch or an inch and half long, from nine to twelve-flowered, (seven to eleven, *Leers*) pressed to the stalk. Valves of the *corolla* equal in length, the lower nerved, the nerves towards the top frequently coloured, at top membranous, rather blunt, with uneven points: the upper valve more pointed, flat and bifid. *Nectary* a small heart-shaped gland resembling a scale, placed horizontally at the bottom of the germ. *Stigmas* very much branched; but the styles not feathered to the germ, as in Schreber's figure and in the Flora Danica. *Seed* shining, olive-coloured, with two little horns, and naked.—When it has nearly done flowering, the branches of the panicle generally project from the main stalk in an acute angle. In every situation, the spikelets are always pressed close to the stalk or branches of the panicle; this circumstance, joined to the length and roundness of the spikelets, sufficiently characterizes this species; which being common in ditches, watery places, and slow streams; flowering all the summer; and having the parts of fructification beautiful and large enough to be distinctly discerned by the naked eye, without the trouble of dissection, is peculiarly proper for the investigation of the student [5].

It appears that horses, kine and hogs are fond of this grass. Mr. Stillingfleet informs us, that hav-

[1] Linn. spec. [2] Leers. [3] Linn. [4] Thunberg. [5] Curtis.

ing

ing been told of a field of four acres, always under water, maintaining five farm horſes in good heart from april to the end of harveſt, without any other food; he obtained ſome of the graſs, and found it to be the *flote-feſcue*, with a mixture of marſh-bent. Cows in ſpring are frequently enticed into bogs, by endeavouring to get at the ſweet young ſhoots of this graſs, which appear earlier than thoſe of moſt other graſſes. Profeſſor Kalm, obſerving that ſwine go a great way into the water after the *flote-feſcue*, and that they eat the leaves with great eagerneſs; had ſmall bundles of it gathered, and dried for hay, which they devoured with great eagerneſs: hence he concludes that wet and ſwampy places might be rendered uſeful by cultivating this graſs. It has been recommended to be ſowed on meadows that admit flooding: but Mr. Curtis juſtly remarks, that the *flote-feſcue* will not flouriſh, except on land that is conſtantly under water, or converted into a bog or ſwamp.

The ſeeds are ſmall, but very ſweet and nouriſhing. They are collected in ſeveral parts of Germany and Poland, under the name of Manna-ſeeds (*Schwaden*), and are eſteemed a delicacy in ſoups and gruels. When ground to meal, they make bread very little inferior to that from wheat. The bran is given to horſes that have the worms; but they muſt be kept from water for ſome hours afterwards.—Geeſe and other water-fowl, are very fond of the ſeeds [g]. So alſo are fiſh; trout in particular thrive in thoſe rivers where this graſs grows in plenty.

Schreber informs us that the ſeeds are collected not only from this graſs, but alſo from *Panicum ſanguinale*, or *Cock's-foot Panic Graſs*, which is cultivated in ſeveral parts of Germany for this purpoſe. The common method of gathering and preparing them is as follows. At ſun-riſe they are gathered or beaten from the dewy graſs into a horſe-hair ſieve, ſpread on a ſheet; and are dried for a fortnight in the ſun; they are then beaten gently with a wooden peſtle in a wooden trough or mortar, with ſtraw laid between them and the peſtle, till the chaff comes off, and then they are winnowed. After this, they are again put into the mortar or trough, in rows, with dried Marygold flowers, apple and hazel leaves, and pounded till they appear bright; they are then winnowed again, and being made perfectly clean by this laſt proceſs are fit for uſe. The Marygolds are added to give the ſeeds a finer colour. The moſt proper time for collecting this ſeed is in july. A buſhel of ſeed with the chaff yields only about two quarts of clean ſeed.

Mr. Curtis has obſerved a diſorder in the ear of this graſs, ſimilar to that which has been noticed by the French in Rie, and called by them *Ergot*.

What Mr. Hudſon diſtinguiſhed in the firſt edition of his Flora, under the name of *F. loliacea*, he afterwards ſuppoſed to be only a variety, from a dry ſoil acquiring acuminate glumes to the floſcules. He alſo aſſerted that flote-feſcue ſown in a garden will become *F. loliacea*. In this however he ſeems to have been miſtaken. F. loliacea being either a diſtinct ſpecies, or elſe a variety of F. pratenſis, which is always very different from F. fluitans or Flote Feſcue; a variety of which frequently occurs on dry land, that may eaſily be diſtinguiſhed from F. pratenſis [h]: it is in every reſpect leſs, and the panicle is often changed to a ſimple ſpike [i].

16. *Meadow Feſcue-Graſs* differs from elatior n. 8. with which it has frequently been confounded, in having only half the height or little more, the leaves only half the breadth, the panicle ſhorter and containing about half the number of flowers; the panicle is but once branched, droops but ſlightly, leans to one ſide when in flower, and the flowers all grow one way; in the *elatior* the panicle branches twice, it droops greatly at firſt, and the flowers grow much more looſely, the ſpikelets are more round, ovate and pointed, whereas in *pratenſis* they are ſomewhat flat, linear and obtuſe. This alſo is more common and leſs local than the *elatior*, is found more diſperſed in open meadows, and does not form ſuch large tufts. They differ a fortnight or three weeks in their time of flowering [k].

Mr. Hudſon, who in the firſt edition of his Flora Anglica gave this as a diſtinct ſpecies, afterwards that the Flote feſcue ſown in a garden, and becoming *F. loliacea* or *Darnel Feſcue*, the firſt year; will in the ſecond become this graſs: than which nothing can be much more improbable. Mr. Curtis, who has cultivated it, recommends it among the ſix Graſſes, which he preſers before all others, and particularly for land either moiſt or moderately dry. This, he ſays, comes neareſt in its appearance to Ray-graſs (*Lolium perenne*), to which however it ſeems in many reſpects greatly ſuperior, at leaſt for the purpoſe of forming or improving meadows: it is larger, and more productive of foliage, is ſtrictly perennial, very hardy, is found in all ſituations, from the ſand-pits at Charlton, to the oſier-grounds at Batterſea, and abounds in the very beſt meadows about London: in ſhort there is no graſs more likely to ſupply the deficiencies complained of in Ray-graſs. One quality it has, which bids fair to introduce it quickly into general uſe; it produces more ſeeds than any of the others, which are eaſily gathered, and readily grow. In one reſpect, it is inferior to *Vernal, meadow Fox-tail*, and *ſmooth-ſtalked Meadow-graſs* (Poa pratenſis); it does not produce its flowering-ſtems earlier than about the middle of june, a fortnight or three weeks later than *meadow Fox-tail Graſs*; yet it cannot be conſidered as a late graſs, for moſt of the *Agroſtis* genus, and *meadow Cat's-tail Graſs* (Phleum pratenſe) flower at leaſt three weeks later. It muſt be carefully diſtinguiſhed from *F. elatior* (n. 8), which is very ſimilar, but much coarſer.

17. Culms many, ſcarcely the length of a finger. Panicle reſembling a ſpike, almoſt ovate, differing from *Aira criſtata* in having more floſcules, and thoſe hirſute, the culm alſo is ſhorter: but it approaches that graſs in its appearance.—Native of Portugal, on barren hills [l].

18. Root annual. Root-leaves collected into a tuft. Culm filiform, narrow, of a finger's length. Panicle attenuated. Calyx the length of the ſpikelet [m].

According to Cavanilles, who obſerved it near Madrid, a ſhort fibrous root produces ſlender culms from four to ſix inches in height, ſomewhat proſtrate at the baſe, but from the firſt joint upright; joints purple. Leaves ſhort, acute, bearded at the tip of the ſheath. Panicle contracted, hardly an inch long. Calycine valves ovate-acute, keeled, rigid, ſtriated, with a ſcarioſe white border, the length of the ſpikelet. Valves of the corolla awnleſs: the outer ovate, ſtriated, white and ſcarioſe at the tip, including the inner. The genitals ſo minute as not to be viſible to the naked eye.

Native of Spain. Flowering there in may; here in june and july. It was introduced in 1781, by Monſ. Thouin [n].

19. Culm lying on the ground, erect at top, a foot and half in height. Leaves enſiform, ſmooth, a finger's length. Panicle reſembling a ſpike, moſtly pointing one way, ſmooth, a finger's length. Calycine glumes containing few flowers.

Native of Japan [o].

20. *Culms* perennial, the ſize of a pigeon's quill feather, ſolid, proliferous; the branches crowded, upright, ſimple, thorny at the end. *Leaves* with dilated ſheaths, ending in an awl-ſhaped pungent, very ſhort leaf. *Branches* round, leafleſs; branchlets alternate, horizontal, very ſimple, an inch long, dagger-pointed and thorny, flat above, roundiſh underneath, pungent-thorny, on both edges; ſpikelets four to ſix formed from the peduncles. *Flowers* diſtich. *Spikelets* ſomewhat oblong, containing ſeven to ten floſcules, not very cloſely approximating,

[g] Withering, and Linn. ſpec. [h] Woodw. Mſs. [i] Curtis. [k] Curtis. [l] Linn. ſpec. [m] Ibid. [n] Hort. kew. [o] Thunberg.

ſcarcely acute. *Peduncle* of the ſpike adhering; the branchlets after the pedunceles fall changing into a ſpinule. Native of the Cape of Good Hope[r].

21. *Root* annual. *Culms* many from ſix inches to a foot in height, oblique, round, ſmooth, ſomewhat branched. *Leaves* petioled, ſomewhat involute, ſharp, naked, much ſhorter than the petiole, which is ſheathing, ventricoſe and naked. *Stipule* membranaceous ſomewhat obtuſe. *Spikelets* peduncled, linear, with from four to eight flowers. *Pedunctles* ſhort, thickening, ſcabrous. *Glume* one-valved, linear, concave, awned. *Corolla* the outer valve larger, linear, keeled, awned, ſcabrous; inner ſhorter, linear, flat, awnleſs. *Awn* twice as long as the floſcule.

Sea coaſt, in looſe ſand; flowering in may and june[s]. Found by Dr. Sherard in Jerſey, by Mr. Dale in Merſey iſland, and by Dillenius on the coaſt of Suſſex[t].

22. *Root* perennial. *Culm* about a foot in height, oblique, round, leafy, ſmooth, having two or three joints. *Root-leaves* ſomewhat erect, enſiform, ſharpiſh, channelled: *ſtem-leaves* two or three, petioled, ſharpiſh, nerved. *Petiole* ſheathing, cylindric, ſtreaked, inflate. *Stipule* membranaceous, ſheathing, obtuſe. *Panicle* ſomewhat condenſed, branched at the baſe. *Spikelets* peduncled, with about ſix flowers, ovate, ſubulate-awned, ſmooth; the awn ſhort. *Pedunctles* almoſt the length of the ſpikelet.—Allied to *F. durinſcula*.

On the higheſt mountains about Llanberis, in Wales, plentifully. It flowers in july and auguſt[u].

23. This ſpecies has the appearance of a *Poa*. *Culms* three feet high and more, the thickneſs of a pigeon's quill, ſtreaked, leafy. *Leaves* linear, the ſheaths ſwelling at the baſe. *Panicle* half a foot in length: the branches ſimple. *Spikelets* ſix to eight-flowered, ſmall, alternate, with ſhort pedicels. *Calyx* the outer valve larger, keeled; the inner ſmaller, flat. *Corolla* glumes nearly equal, ſmooth, the nerve of the outer uſually ending in a ſhort awn. It is diſtinguiſhed from far by its blueiſh green colour. One half of the panicle flowers and expands, then contracts whilſt the other half flowers. Native of Tranquebar in the Eaſt Indies, in the rice-grounds: with erect culms in flooded lands, and decumbent ones in dry places[v].

24. This graſs is a foot and half high, or more, with a round, ſmooth, ſtriated culm, and involuted leaves. Panicle a long ſpan in length, upright; the lower branches ſubdivided. Spikelets lanceolate. Calycine glumes ſmooth. Outer valves of the corolla rugged, acute, villoſe when viewed by a magnifier.

Native of the Cape of Good Hope, whence it was ſent by Bulow.

25. Culm creeping. Branches erect, divided at top commonly into four divaricated branchlets, a ſpan long, and the thickneſs of a pigeon's quill: the internodes an inch in length. Leaves alternate, in two rows ſpreading very much, pungent, very ſmooth, very finely ſtreaked. Sheaths twice as long as the joints, covering the culm, broader than the leaves, ciliate, bearded at the throat on each ſide; without any ligule or ſtrap. Spike compound, ſeſſile, terminating, half an inch long. Rachis pubeſcent. Spikelets twelve, alternate, glomerate. Calyx from ſix to eight-flowered; valves oblong, concave, ſmooth, keeled, awnleſs, one narrower than the other. Outer valve of the corolla ovate, concave, mucronate, hyaline with three elevated green lines, ſlightly ſerrulate at the tip, hairy on the outſide, eſpecially at the baſe and towards the edge: inner valve narrower, flat, the ſides bent in hairy, with a green line on both ſides at the edge[w].

26. In deference to the judgment of Mr. Curtis, who has beſtowed ſo much laudable attention on this uſeful tribe of Graſſes, the *Darnel* Feſcue-graſs is here given as a diſtinct ſpecies, though Mr. Hudſon regarded it as a variety of the *fluitans*, and others the *pratenſis*[x].

In root, ſtalk, leaves and habit it comes ſo near Lolium perenne (or common Ray-graſs) as ſcarcely to be diſtinguiſhed from it, but it is uſually higher by about one-third; the flowers in general grow in a ſimple ſpike, from eight inches to a foot in length, bending a little towards the top; the ſpikelets are ſeſſile, near an inch long, diverging from and for the moſt part placed obliquely to the rachis, ſometimes on pedunctles of different lengths, the lowermoſt about an inch long, nearly round, flattened a little on the ſides, running out to a point; the uppermoſt ſhorter and ſomewhat broader, containing from ten to fifteen flowers; calycine valves unequal in ſize, the innermoſt frequently ſmall, lateral, and ſometimes wanting.

The ſpike is not unfrequently branched; then it approaches nearer to *F. pratenſis*, but may be diſtinguiſhed from it by the length of its ſpiked panicle; moſt commonly the branches grow from the baſe of the ſpike, ſometimes from the middle, but ſometimes the ſpikelets are ſhorter, and two or three grow together from the ſame point: when the ſpikelets are ſhorter and broader than uſual, it reſembles Lolium perenne ſo much, as frequently to be taken for the ſame; and may be conſidered indeed as forming the connecting link between that genus and this. In this ſtate however it may be diſtinguiſhed, 1. By the ſpikelets being placed obliquely to the rachis, whereas in the Lolium their edge is parallel with it, which gives the ſpike a flat appearance. 2. Lolium never has more than one valve to the calyx, which is ſtrong and u ually two-thirds of the length of the ſpikelet; whereas in this there are uſually two calycine valves, though the inner valve is often very ſmall, imperfect, and ſometimes wanting altogether; but it rarely happens that it is deficient in all the ſpikelets. 3. The outer valve of the calyx is rarely more than one-third of the length of the ſpikelet.

It is found plentifully in moiſt fertile meadows, and flowers about the ſame time with the *pratenſis*. It is a hardy perennial of very quick growth, producing a crop ſomewhat ſimilar to Ray-graſs, but larger, and ſucceeding beſt in a moiſt ſoil; it is however harſh and ſtalky. This and the elatior do not ſeem to produce ſeeds, in a ſtate of cultivation at leaſt[y]. May not this circumſtance ariſe from their running much at the root?

Leaves lobed, dotted underneath.
2. Feuillea cordifolia.
Lin. fyst. 887. *Reich.* 253. *Brown. jam.* 374. *Swartz obs.* 377.
Leaves heart-shaped, angular.

DESCRIPTIONS, &c.

These are climbing herbs, with alternate leaves, heart-shaped or three-lobed, cirrhouse in the axils; the pedunckles are axillary, sustaining one or many small flowers. It is doubtful whether these be really monopetalous, or rather apetalous, with the inner calyx coloured, as in other cucurbitaceous plants, to which this genus is nearly allied. The star which closes the opening of the male flower is probably the triple permanent style of an abortive germ. There are ten distinct filaments alternately fertile and barren. The star in the female flower, is perhaps made up of abortive stamens. The fruit is a berry, half inferior, spherical, scored round with a circular vestige of the border of the calyx: it is three-celled, and contains many seeds, which are large, and covered with a corky cruft; the heart is large, without any perisperm [a].

1. Stem angular, the thickness of a thread. Leaves petioled, cordate, five-parted, naked, the upper surface rugged, but the lower is so only on the veins: middle lobes dilated-three-lobed, lateral ones shorter, blunter, two-lobed; all punched beneath with honey pores. At the axils of the leaves are tendrils and bulbs [b]. Native of the East-Indies.

2. Stem suffrutescent at bottom, divided at top, with herbaceous branches, (as in the three-lobed) climbing frequently to the tops of trees, roundish, and very smooth. Leaves petioled, alternate, usually cordate, when more adult cordate-lobed, the lower ones three-lobed, the lobes angular, thick, nerved, very smooth on both sides. Flowers racemed, dusky yellow.

Racemes in the male, divaricating, loose; the subdivisions almost upright, alternate, many-flowered; flowers pedicelled. Calyx five-parted; the parts convex, spreading, ovate, dusky. Filaments converging at the base, reflex, club-shaped, gibbous, with a sort of head at the end, to which the anthers are fastened: these are ovate, open longitudinally in the middle, and are whitish. The five other threads forming the nectary are yellow. The fruit is a globular, corticose, hard, many-seeded pome. The nuts are orbicular, compressed, rugged and ferruginous, inclosing a very white kernel. The whole plant is very bitter. There is a remarkable analogy between the fruit of this plant and Faba Ignatii [c].

It is frequent in the inland parts of Jamaica, and is generally found climbing among the tallest trees in the woods. The seeds are very oily, and often burnt by the negroes instead of candles. The kernels are extremely bitter, and commonly infused in rum for the use of the negroes: a small quantity of this liquor opens the body and provokes an appetite, but a larger dose works both by stool and vomit. It is frequently taken when there is any suspicion of poison, and often on other occasions [d].

Browne calls it the Antidote Cocoon.

[a] Jussieu. [b] Linn. amoen. [c] Swartz. [d] Browne.

The first species is a native of the East-Indies; but it is doubtful whether they be distinct. Swartz affirms, that they are not so much as varieties.

Nat. order of *Scabridæ—Urticæ.* Juss.

GENERIC CHARACTER.

CAL. *common* obovate, very large, fleshy, concrete; closed with very many semilanceolate, sharp, erect, inflex *scales.* The inner surface is covered with *fascules*, the outer of which, or those which are nearest to the edge of the calyx, are *male*; these are fewer in number: the reft, lower down, are *female*, and more numerous.

Male, each on its proper pedunckle.

CAL. *Perianth proper* three-parted, *erect* (bell-shaped, trifid. *G.*): *divisions* lanceolate, erect, equal.
COR. none.
STAM. *Filaments* three, bristle-shaped, length of the calyx. *Anthers* twin.
PIST. *Rudiments* caducous, inserted.

Female, each on its proper pedunckle.

CAL. *Perianth proper* five-parted (bell-shaped, quinquefid. *G.*): *divisions* lanceolate-acuminate, straight, nearly equal.
COR. none.
PIST. *Germ* (half inferior, *G.*) oval, the size of the proper perianth. *Style* subulate (bristle-shaped, *G.*), inflex, coming out from the germ at the side of the tip. *Stigmas* two, acuminate, reflex, one shorter than the other.
PER. none. *Calyx* oblique, containing in its bottom a seed, larger?
SEED single, roundish, compressed.

OBS. Capparides *comprehends within a common calyx only male flowers within a distinct plant.*
Erinosyce *has some flowers compound male, others female, on a distinct plant.*

ESSENTIAL CHARACTER.

Receptacle common turbinate, fleshy, converging, concealing the floscules, either on the same or a distinct individual.
MALE. *Cal.* three-parted. *Cor.* none. *Stam.* three.
FEM. *Cal.* five-parted. *Cor.* none. *Pist.* one. *Seed* one.

SPECIES.

Leaves cordate, roundiſh, quite entire, tomenteſe underneath, fruits ſeſſile.

3. Ficus nymphæifolia. *Water-lily-leaved Fig-tree. Lin. ſyſt. 921. Reich. 365. mant. 305. hort. cliff. 471. n. 3.*

F. nymphoides. *Thunb. Ficus n. 2.*

Leaves ovate, cordate, mucronate, quite entire, ſmooth, glaucous underneath.

4. Ficus religioſa. *Poplar-leaved Fig-tree. Lin. ſpec. 1514. Reich. 365. mant. 504. hort. cliff. 471. amœn. 1. 30. n. 16. Thunb. mon. n. 3. Gærtn. fruct. 2. 484. Lour. cochinch. 665. Pluk. alm. t. 178. f. 2. Rheed. mal. 1. 47. t. 27. Raii hiſt. 1434.*

Leaves ovate, cordate, cuſpidate, ſmooth, fruits ſeſſile.

[5. Ficus benjamina. *Oval leaved Fig-tree. Lin. ſyſt. 921. Reich. 366. mant. 129. 519. Thunb. mon. n. 15. Lour. cochinch. 665. Pluk. alm. t. 243. f. 4. Rheed. mal. 1. 45. t. 26. Rumph. amb. 3. 139. t. 90.*

F. microcarpa. *Lin. ſyſt. 922. ſee n. 23.*

Leaves elliptic, obtuſe, ſmooth, fruits acute, ſeſſile.]

6. Ficus bengalenſis. *Bengal Fig-tree. Lin. ſpec. 1514. Reich. 366. hort. cliff. 471. amœn. 1. 29. Lour. cochinch. 665. Thunb. monogr. n. 5. Trew. ehr. t. 50. Pluk. phyt. t. 178. f. 1. Comm. hort. 1. t. 62. Rheed. mal. 1. 49. t. 28.*

F. vaſta. *Forſk. deſcr. 179.*

Leaves ovate, cordate, quite entire, ſmooth, blunt, coriaceous, ſtem arboreous, erect.

[7. Ficus pedunculata. *Willow-leaved Fig-tree. Ait. hort. kew. 3. 450. Pluk. alm. t. 178. f. 4.*

Leaves ovate-oblong, cordate, quite entire, ſharp, ſmooth, fruits globular, peduncles in pairs, elongated.

8. Ficus lucida. *Shining leaved Fig-tree. Ait. hort. kew. 3. 451.*

Leaves ovate, cordate, quite entire, ſmooth, blunt, three-nerved at the baſe, branches upright.]

9. Ficus indica. *Indian Fig-tree.*

Lin. ſpec. 1514. α. Reich. 366. amœn. 1. 27. n. 6. Thunb. mon. n. 20. Lour. cochinch. 665. Bauh. pin. 457. n. 8. Tabern. hiſt. 1370. Rheed. mal. 3. 73. t. 57. Raii hiſt. 1437. n. 4. Bauh. hiſt. 1. 145. Ger. 1331. emac. 1514. Park. theat. 1499.

Leaves oblong, rounded at the baſe, ſmooth and even, quite entire, ſomewhat glaucous underneath, impreſſed with dots above, fruits almoſt globular.

10. Ficus virens. *Round-fruited Fig-tree. Ait. hort. kew. 3. 451. Sloan. jam. 2. 140. t. 223. Raii dendr. 16. 5. Brown. jam. 110. n. 5? Lin. amœn. 1. 28. n. 14.*

F. indica. β. *Lin. ſpec. 1514.*

F. maxima. *Mill. dict. n. 6.—*& citrifolia, *n. 10?*

Leaves oblong, acuminate, quite entire, ſmooth and even, narrowed and rounded at the baſe.

[11. Ficus venoſa. *Waved-leaved Fig-tree. Ait. hort. kew. 3. 452. Rheed. malab. 3. 87. t. 64.*

Leaves ovate, ſomewhat cordate, ſharp, quite entire, ſmooth and even, impreſſed with dots on the upper ſurface.

12. Ficus coſtata. *Upright heart-leaved Fig-tree. Ait. hort. kew. 3. 452.*

Leaves ovate, cordate, with a deep narrow ſinus; quite entire, ſmooth, ſharp, green on both ſides.]

13. Ficus racemoſa. *Red-wooded Fig-tree. Lin. ſpec. 1515. ſyſt. 922. Reich. 367. amœn. 1. 30. n. 17. Thunb. mon. n. 17. Rheed. mal. 1. 43. t. 25. Raii hiſt. 1434. 1.*

Leaves ovate, quite entire, ſharp, impreſſed with dots; ſtem arboreous.

[14. Ficus pertuſa. *Laurel leaved Fig-tree. Lin. ſyſt. 922. ſuppl. 442. Thunb. monogr. n. 13. Rheed. mal. 3. t. 56?*

Leaves ovate, ſmooth, calyxes bifid, berries globular, umbilicated with a hole.

15. Ficus retuſa. *Blunt-leaved Fig. Lin. ſyſt. 922. Reich. 367. mant. 129. Thunb. mon. n. 18.*

Leaves obovate-oblong, extremely obtuſe, branches angular, fruits ſeſſile.]

16. Ficus pumila. *Lin. ſpec. 1515. Reich. 368. amœn. 1. 30. n. 15. Thunb. monogr. 10. jap. 33. Kæmpf. amœn. 803.* (Itabu.) *Lour. cochinch. 667? Burm. ind. 226.*

Leaves oblong-ovate, blunt, ſmooth, netted underneath, ſtem decumbent, fruits peduncled.

[17. Ficus toxicaria. *Lin. ſyſt. 922. Reich. 368. mant. 305.*

F. toxica. *Thunb. monogr. n. 27.*

F. padana. *Burm. ind. 226.*

Leaves cordate-ovate, ſomewhat tootbletted, tomenteſe underneath.

18. Ficus maculata. *Lin. ſpec. 1515. Reich. 368. Lour. cochinch. 666. Plum. ſpec. 21. ic. 131. f. 1. Burm. ind. 226.* (ſee n. 20.)

Leaves oblong, acuminate, ſerrate.

19. Ficus trigona. *Lin. ſyſt. 922. ſuppl. 441. Thunb. monogr. n. 12. Plum. ic. 123. t. 132. f. 1.*

Leaves elliptic, calyxes bifid, berries with a triangular navel.

20. Ficus hiſpida. *Lin. ſyſt. 922 ſuppl. 442. Thunb. monogr. n. 24.*

Leaves oblong, petioled, ſharp, fruits ſcrigoſe-hiſpid.

21. Ficus ſtipulata. *Trailing Fig-tree. Ait. hort. kew. 3. 452. Thunb. monogr. n. 7.*

Leaves obliquely cordate, obtuſe, ſmooth, ſtem decumbent, ſcaly.

22. Ficus heterophylla. *Rough-leaved Fig-tree. Lin. ſyſt. 922. ſuppl 442. Thunb. monogr. n. 25. Rheed. mal. 3. 83. t. 62.*

Leaves oblong, undivided, three-lobed and ſinuate, ſcabrous, ſtem hiſpid, fruit ovate, peduncled, ſcabrous.

23. Ficus microcarpa. *Lin. ſyſt. 922. ſuppl. 442.*

Leaves oblong, on ſhort petioles, three-nerved, veined, very ſmooth, fruit globular, ſmall, ſeſſile.

24. Ficus coriacea. *Leathery-leaved dwarf Fig-tree. Ait. hort. kew. 3. 453.*

Leaves oblong, ſmooth and even, attenuated at the baſe, cordate, leathery, veins immerſed.

25. Ficus ſcabra. *Forſt. fl. auſtr. n. 403.*

Leaves cordate-ovate, oblique, entire, ſcabrous underneath, fruits turbinate, without calyxes.

26. Ficus aſpera. *Forſt. pl. eſcul. 7. fl. auſtr. n. 404. Thunb. monogr. n. 4.*

Leaves obliquely cordate, ſinuate-toothed, rough on both ſides, fruits turbinate, the edge of the calyx obſcure, and growing to them.

27. Ficus tinctoria. *Forſt. fl. auſtr. n. 405.*

Leaves obliquely ovate, obtuſe, fruits turbinate, calycled at the baſe.

28. Ficus ſeptica. *Forſt. fl. auſtr. n. 407.*

Leaves oblique, oblong-ovate, acuminate, peduncles in pairs, calycled at the tip, fruits warted.

29. Ficus Granatum. *Forſt. fl. auſtr. n. 408. eſcul. 37.*

Leaves ovate, quite entire, peduncles terminating in pairs, horizontally diverging, fruits calycled, globular.

30. Ficus obliqua. *Forſt. fl. auſtr. n. 409.*

Leaves lanceolate, very ſmooth, cartilaginous at the edge, peduncles in pairs, very ſhort, calyxes caducous, the length of the fruit.

31. Ficus prolixa.
Forſt. fl. auſtr. n. 410.
Leaves lanceolate-oblong, acuminate, dotted underneath, peduncles in pairs, calycled at the tip.]
32. Ficus calyculata.
Mill. dict. n. 11. *Houſt. Mſs.*
Leaves ovate, quite entire, obtuſe, oppoſite, fruit globular, calycled.
[33. Ficus americana.
Swartz prodr. 127. *Aubl. guian.* 2. 952. *Plum. ſpec.* 124. *t.* 132. *f.* 2. *Sloan. jam.* 2. 140. *n.* 5. *Raii dendr.* 16.
Leaves ovate, oblong, veined, quite entire, fruits axillary, peduncled, cluſtered.
34. Ficus erecta.
Thunb. monogr. 11. *in Linn. tranſ.* 2. 327. *Kæmpf. ic. ſelect. t.* 2.
F. pumila. *Linn. ſyſt.* 922. *β. Thunb. jap.* 33.
Leaves oblong, acute, ſmooth, netted beneath, ſtem decumbent, with upright branches, fruits peduncled.
35. Ficus ſtipulata.
Thunb. monogr. n. 7. *Linn. tranſ.* 2. 327.
Leaves obliquely cordate, obtuſe, ſmooth, ſtem decumbent, ſcaly.
36. Ficus auriculata.
Lour. cochinch. 666. *Rumph. amb.* 3. *t.* 93.
Leaves heart-ſhaped, acuminate, fruit eared, racemed, terminating.
37. Ficus politoria.
Lour. cochinch. 667. *Rumph. amb.* 3. *t.* 63. *Burm. ind.* 226.
Leaves oblong-ovate, quite entire, rugged, fruit roundiſh, in ſpikes, ſtem erect.
38. Ficus ſimpliciſſima.
Lour. cochinch. 667.
Leaves palmate, ſtem quite ſimple, fruit compreſſed.
39. Ficus cannabina.
Lour. cochinch. 668.
Stem-leaves haſtate, gaſhed, branch-leaves ovate-lanceolate, ſubſerrate, ſtem ſuberect.
40. Ficus populifolia.
Vahl ſymb. 1. 82. *t.* 22.
F. religioſa. *Forſk. deſcr.* 180.
Leaves finely cordate, acute, fruits in pairs, pedicelled.
41. Ficus mollis.
Vahl ſymb. 1. 82.
Leaves oblong, quite entire, villoſe underneath, fruits axillary, ſeſſile, tomentoſe.
42. Ficus ſalicifolia.
Vahl ſymb. 1. 82. *t.* 23.
F. indica. *Forſk. deſcr.* 179.
Leaves lanceolate, acuminate, fruits in pairs, axillary, peduncled.
43. Ficus ſagittata.
Vahl ſymb. 1. 83.
Leaves heart-ſhaped, oblong, acute, rugged on both ſides, ſtem creeping.
44. Ficus denticulata.
Vahl ſymb. 1. 83.
Leaves oblong, undivided, three-lobed and ſinuate, toothletted, rugged, fruit peduncled, muricated, globular.
45. Ficus truncata.
Vahl ſymb. 1. 83.
Leaves oblong, undivided and lobed, quite entire, rugged, fruits peduncled, oblong, truncated, rugged.
46. Ficus ſerrata.
Vahl ſymb. 1. 83. *Forſk. deſcr.* 179.
Leaves oblong, undivided and palmate, repand-toothed, rugged, fruit peduncled, globular, very rugged.
47. Ficus palmata.
Vahl ſymb. 1. 84. *t.* 24. *Forſk. deſcr.* 179.
Leaves cordate-ovate and lobed, ſerrate, fruits pear-ſhaped, peduncled, ſmooth.
48. Ficus cordata.
Thunb. monogr. n. 6.
Leaves ſubcordate, ovate, acute, ſmooth, coriaceous, ſtem ſhrubby, erect.
49. Ficus falcata.
Thunb. monogr. n. 8.
Leaves oblong, ſickle-ſhaped, ſmooth, ſtem filiform, rooting.
50. Ficus punctata.
Thunb. monogr. n. 9.
Leaves oblong, emarginate, ſmooth, dotted underneath, ſtem flexuoſe, rooting.
51. Ficus nitida.
Thunb. monogr. n. 14.
Leaves elliptic, acute, ſmooth, fruits retuſe-umbilicate, ſeſſile.
52. Ficus reflexa.
Thunb. monogr. n. 16.
Leaves elliptic, obtuſe, ſmooth, branches recurved, fruits globular, ſeſſile.
53. Ficus drupacea.
Thunb. monogr. n. 19.
Leaves obovate, cuſped, ſmooth, fruits ovate, wrinkled, ſeſſile.
54. Ficus reticulata.
Thunb. monogr. n. 21.
Leaves elliptic, ſomewhat angular, cuſped, ſmooth, netted underneath, fruits globular, ſolitary, peduncled.
55. Ficus ſinuata.
Thunb. monogr. n. 22.
Leaves elliptic, ſinuate-toothed, cuſped, ſmooth, fruits globular, aggregate, peduncled.
56. Ficus capenſis.
Thunb. monogr. n. 23.
Leaves ovate, acute, ſmooth, ſerrate, fruits peduncled, ſmooth.

DESCRIPTIONS, *&c.*

Linneus tells us, that he removed this genus from the claſs Cryptogamia to Polygamia, on account of the different ſtructure of the fructification, the ſpreading *umbilicus*, navel, or opening of the receptacle in ſome ſpecies, its want of genuine affinity to the plants of the claſs Cryptogamia, and by the advice of Baron Munchauſen, a very acute Botaniſt. Some modern authors have again removed the genus into the claſs *Triandria*.

There are two treatiſes expreſsly on this genus, one in the firſt volume of the Amoenitates Academicæ, in 1744; and the ſecond by Thunberg in 1786.

Figs are either trees or ſhrubs, abounding in a milky juice; the branches alternate; the leaves alſo alternate, when young incloſed within ſheathing ſtipules convoluted into a terminating horn, frequently ſoon caducous, and the veſtiges of them remaining: fruit turbinate or globular, often axillary, either ſolitary or crowded, either ſeſſile or peduncled, ſometimes but ſeldom in terminating bunches[a].

Fruit, according to the deſcription of Gærtner, turbinate, umbilicate at the top, fleſhy, ſoft, hollow within. The pericarp is a very ſmall berried drupe, or rather utricle, on a filiform peduncle, covered with the calyx above the middle, and terminated by the permanent ſtyle: rind fleſhy-gelatinous, ſub-pellucid, finally drying up; ſhell cruſtaceous, ſlender, brittle, reſembling a ſeed, which is of the ſame ſhape, namely ovate, narrowing upwards, compreſſed like a lens, with an umbilical hole below the tip; the embryo ſomewhat cylindric, hooked, inverted, the lobes ſemi-cylindric, lying down, bowed[b].

The common Fig-tree is, in all probability, originally a native of Aſia, though it has been introduced into Europe in the very early ages; the Sycomorus is the growth of Egypt: ſome of the other ſpecies are found in South America and the Eaſt Indies, two at the Cape of Good Hope, three in Japan, and ſome in the South Sea iſlands; but the greater part are natives of the Eaſt Indies; the fruit of moſt of them is ſmall and uſeleſs for eating.

1. The common Fig-tree ſeldom exceeds two yards in height. The trunk is about the thickneſs of the human arm; the wood porous and ſpongy, the bark aſh-coloured, full of chinks, and rugged. Branches ſmooth, with oblong white dots, erect or aſcending, flexuoſe, and bent back. Stipules in pairs, ſeſſile, ovate, acute, ferruginous, caducous.

[a] Juſſieu. [b] Gærtner.

Leaves

Leaves annual (in Europe, but within the tropics perennial) cordate, ovate, three or five-lobed, with rounded ſinuſes, ſerrate-toothed, paler underneath, rugged on both ſides, ſpreading, the ſize of the hand, or a ſpan in length. Petioles round, grooved, about an inch in length. Fruits axillary, ſolitary, the ſize of a pear, on very ſhort round pedunckes [c]. Cordus firſt remarks the flowers produced within the fruit [d].

The Fig-tree has the ſame name in all the European languages, but little varied. In German, *Feigenbaum* or *Figenbcom*. In Daniſh, *Figentræ*. In Swediſh, *Fikonträ*. In French, *Le Figuier*. In Italian, *Fico* or *Figo*. In Spaniſh, *Higuéra*. In Portugueze, *Figueira*. In Ruſſian, *Finik*. In Poliſh, *Figa*. In Turkiſh it is *Ingir*. In Arabic, *Tin*.

Native of Aſia, Barbary, the ſouthern parts of Europe, Louiſiana, &c.

The firſt figs introduced into England are ſtill remaining in the Archbiſhop's garden at Lambeth. They are of the white Marſeilles kind, and ſtill bear delicious fruit. They cover a ſurface of fifty feet in height, and forty in breadth. The circumference of the trunk of the ſouthernmoſt is twenty-eight inches, of the other twenty-one. On the South ſide of the building is another tree of the ſame age; its circumference at bottom twenty-eight inches. Tradition ſays, they were planted by Cardinal Pole, and it is very probable; for it is generally allowed that Fig-trees were brought into England in the reign of Henry the Eighth, and it ſeems likely that the Cardinal, who had long reſided in Italy, ſhould be fond of cultivating thoſe fruits to which he had been there accuſtomed [e]. To the objection ariſing from their great age, it may be anſwered, that we do not well know how long a Fig-tree will flouriſh, if properly cultivated. There is alſo a concurrent tradition of an older tree, and inſtances of two very ancient ones, the times of whoſe plantation is well aſcertained.—1. At Mitcham, in the garden of the Manor-houſe, formerly the private eſtate of Archbiſhop Cranmer, and now belonging to one of his deſcendants. It is likewiſe of the white ſort, and is confidently aſſerted to have been planted by Archbiſhop Cranmer. Its branches are very low, but its ſtem, which meaſures thirty inches in girt, has every mark of great age [f].—2. In the Dean's garden at Wincheſter, there was in the year 1767 a very ancient Fig-tree, whoſe fruit was of the ſmall red ſort. It was incloſed in a wooden frame, with a glaſs door and two windows on each ſide of it for the admiſſion of ſun and air. The frame protected it from wind and rain. On the ſtone wall to which the tree was nailed there was a plaiſtering, and ſeveral inſcriptions, one of which mentioned, that in the year 1623 King James I. "taſted of the fruit "of this tree with great pleaſure." It has been ſuffered to periſh for want of neceſſary repairs to the frame-work.—3. At Oxford, in the garden of the Regius Profeſſor of Hebrew, is a Fig-tree brought from the Eaſt, and planted by Dr. Pocock in the year 1648. It is in a thriving condition, and bears a black fig [g].

I was informed (nov. 18. 1792.) by the learned Dr. John Sibthorp, late Regius Profeſſor of Botany at Oxford, that it bears the marks of great age; that the trunk is perforated by inſects, and damaged by time and weather; but that the branches of the new wood were clean, made vigorous ſhoots, and produced a number of ſmall figs, which were touched by the froſt, and were then falling off. The fruit is not, as Groſe aſſerts, *black*, but *white*.

We learn alſo from Turner's herbal, that the Fig was cultivated here in 1562 [h]. Gerarde ſays, in 1597, "that the fruit never cometh to kindly ma-

[c] Thunb. diſſ. de Ficu. [d] Linn. amœn.

[e] Cardinal Pole returned from Italy to England in 1525.

[f] It has been demoliſhed ſeveral years. 1792.

[g] Groſe's antiqu. vol. 3. and Daicarrel's hiſt. of Lambeth palace, p. 77. 78. by whom the above particulars were communicated in 1773.

[h] Hort. kew.

"turity with us, except the tree be planted under ſtil "hot wall, whereto neither north nor north-eaſt "winds can come." Parkinſon alſo in 1629 ſays, "that if you plant it not againſt a brick wall, or the "wall of an houſe, it will not ripen ſo kindly; that "the dwarf fig is more tender, and is therefore planted "in great ſquare tubs, to be removed into the ſun "in the ſummer time, and into the houſe in winter." In his time only three ſorts were known. "1. Figs "of Algarva, ſweet and delicate, blewiſh when ripe. "2. The white ordinary ſort that cometh from Spain. "3. The dwarf fig, not higher than a man's ſhoulders, "bearing excellent blew fruit, but not ſo large as the "firſt [i]."]

Mr. Miller informs us, that there are many varieties in the warm countries, which have been obtained from ſeeds, and might be increaſed, if the inhabitants were careful in propagating the trees from the ſeeds of the beſt ſorts. In England we had not more than four or five ſorts till within a few years paſt: for as the generality of the Engliſh were not lovers of this fruit, there were few who troubled themſelves with the culture of it. But ſome years paſt I had a large collection of theſe trees ſent me from Venice, by my honoured friend the Chevalier Rathgeb, which I planted and preſerved to taſte of their fruits, ſeveral of which proved excellent; theſe I have preſerved and propagated, and thoſe whoſe fruit were inferior have been neglected. And as the variety of them is very great, ſo I ſhall here mention only ſuch of them as are the beſt worth cultivating, placing them in the order of their ripening.

1. The brown or Cheſtnut-coloured Iſchia Fig. This is the largeſt fruit of any I have yet ſeen, it is ſhort, globular, with a pretty large eye, pinched in near the foot-ſtalk, of a brown or Cheſtnut colour on the outſide, and purple within; the grains are large, and the pulp ſweet and high flavoured; this ſort very often burſts open when it ripens: which it does the end of july, or the beginning of auguſt. I have had this fruit ripen well on ſtandards, in a warm ſoil. If it is planted againſt hot walls, two plentiful crops of fruit may be annually ripened.

2. The black Genoa Fig. This is a *long* fruit, which ſwells pretty large at the top, where it is obtuſe, but the lower part is very ſlender toward the ſtalk; the ſkin is of a dark purple colour, almoſt black, and has a purple farina over it like that on ſome Plumbs; the inſide is of a bright red, and the fleſh is very high flavoured. It ripens early in auguſt.

3. The ſmall white early Fig. This has a roundiſh fruit a little flatted at the crown, with a very ſhort foot-ſtalk; the ſkin, when fully ripe, is a pale yellowiſh white colour; the ſkin is thin, the inſide white, and the fleſh ſweet, but not high-flavoured. This ripens in auguſt.

4. The large white Genoa Fig. This is a large globular fruit, a little lengthened toward the ſtalk; the ſkin is thin, of a yellowiſh colour when fully ripe, and red within. This is a good fruit, but the trees are not good bearers.

5. The black Iſchia Fig. This is a ſhort fruit, of a middling ſize, a little flatted at the crown; the ſkin is almoſt black when ripe, and the inſide is of a deep red; the fleſh is very high flavoured, and the trees produce a good crop of fruit, but the birds are great devourers of them, if they are not protected. This ripens in auguſt.

6. The Malta Fig. This is a ſmall brown fruit, much compreſſed at the top, and greatly pinched toward the foot-ſtalk; the ſkin is of a pale brown colour, as is alſo the inſide, the fleſh is very ſweet, and well flavoured. If this ſort is permitted to hang upon the trees till the fruit is ſhrivelled, it becomes a fine ſweetmeat.

7. The Murrey, or brown Naples Fig. This is a pretty large globular fruit, of a light brown colour on the outſide, with ſome faint marks of a dirty white, the inſide is nearly of the ſame colour; the

[i] Parad. 567.

grains

grains are pretty large, and the flesh is well flavoured. It ripens the latter end of auguſt.

8. The green Iſchia Fig. This is an oblong fruit, almoſt globular at the crown; the ſkin is thin, of a green colour; but when it is fully ripe, it is ſtained through by the pulp to a browniſh caſt; the inſide is purple, and will ſtain linen, or paper; the flesh is high flavoured, eſpecially in warm ſeaſons. It ripens toward the end of auguſt.

9. The Madonna Fig, commonly called here the Brunſwick, or Hanover Fig, is a long pyramidal fruit of a large ſize; the ſkin is brown; the flesh is of a lighter brown colour, coarſe, and has little flavour. This ripens the end of auguſt, and the beginning of ſeptember; the leaves of this ſort are much more divided than of moſt others.

10. The common blue, or purple Fig, oblong; the tree a great bearer; the fruit ripens in auguſt.

11. The long brown Naples Fig. The leaves of this tree are deeply divided. The fruit is long, ſomewhat compreſſed at the crown. The foot-ſtalks are pretty long; the ſkin is of a dark brown when fully ripe, the flesh inclining to red; the grains are large, and the flesh well flavoured. It ripens in ſeptember.

12. The yellow Iſchia Fig. This is a large fruit, of a pyramidal form; the ſkin is yellow when ripe, and the flesh is purple and well flavoured, but the trees do not produce much fruit here; they grow very luxuriant in branches, the leaves are very large, and not much divided. This ripens in ſeptember.

13. The ſmall Brown Iſchia Fig. This is a ſmall pyramidal fruit, with a very ſhort foot-ſtalk; the ſkin is of a light brown, the flesh inclining to purple, of a very high flavour; it ripens late in ſeptember; the leaves of this tree are leſs divided than any of the other ſorts. This is not a good bearer.

14. The Gentile Fig. This a middle ſized globular fruit; the ſkin, when ripe, is yellow; the flesh alſo inclines to the ſame colour; the grains are large, and the flesh is well flavoured, but it ripens very late, and the trees are bad bearers, ſo that it is not propagated much in England.

There are ſeveral others which have been lately introduced from Italy, but all thoſe which I have yet taſted, are inferior to thoſe above-mentioned; ſome of them rarely ripen their fruit, and others are very ill bearers, not worth propagating, therefore I have omitted the mentioning of them here; for as thoſe which are enumerated, continue in ſucceſſion during the ſeaſon for theſe fruits, and are preferable to the others, few perſons will care to fill their gardens with a greater variety of theſe trees than are of real uſe, eſpecially as they require good walls, and a very large ſhare of room.

2. The Egyptian or Pharaoh's Fig-tree or Sycomore is a large tree, with leaves like thoſe of the Mulberry.

[The ſtem is often fifty feet thick; and as it ſpreads out its boughs very much, it is of great uſe in a ſcorching climate to ſhade thoſe who travel through the deſarts. The Mummies in Egypt are preſerved in coffins of this wood, which is of a redditſh colour, light, and very proper for this uſe, becauſe it does not rot for many ages. The fruit] is produced from the trunk and larger branches, and is ſhaped like the common Fig; it [is pierced by an inſect (Cynipe ſycomori) a little before it ripens, in two different ways; either the ſcales which cover the calyx wither, and are bent back, as in the common fig, for the admiſſion of the inſect; or, which is more common in this ſpecies, a little below the ſcales on the ſide of the involucre the fruit is affected with a gangrene, which extends itſelf, and frequently occupies the ſpace of a finger's breadth; it withers, the place affected becomes black, the fleſhy ſubſtance in the middle is corroded, for the breadth of a quill, and the male bloſſoms, which are neareſt, appear naked, opening a way for the inſect, which makes ſeveral furrows in the inſide of the fruit, but never touches the ſtigmas, though it frequently eats the germs. The gangrænous part is at firſt covered by the bloſſoms, but the hole is by degrees enlarged, of various ſizes, in different fruits, the margin and ſides being always gangrenous, black, hard, and turned inwards. The fruit taſtes pretty well, when quite ripe it is ſoft, watery, ſomewhat ſweet, with a very little portion of an aromatic flavour: though fleſhy enough, yet but little of it is good, the inſects having eaten much of it. At the end of march it buds, and the fruit ripens the beginning of june, the inhabitants wound or cut it when it buds, and ſay that without this precaution it will not bear fruit'. We call it in Engliſh Sycomore tree, and Mulberry Fig-tree. This, and not the great Maple, is the right Sycomore".

Native of Egypt, the Levant and Cochinchina. Cultivated by Mr. Miller in 1736'.]

3. This riſes with a ſtrong, upright, woody ſtem twenty feet high, ſending out ſeveral ſide branches, which have large, oval, thick, ſtiff leaves [as big as thoſe of yellow Water-Lily, waved a little about the edge, blunt with a point, hanging down, as it were peltate, ſmooth, whitiſh underneath',] about fourteen inches long, and near a foot broad, having ſeveral tranſverſe veins: the foot-ſtalks are a ſpan long and more, compreſſed, ſmooth, and frequently turned next to the branches. Native of the Eaſt-Indies; whence it was brought to the gardens in Holland [and cultivated in 1759, by Mr. Miller'.

4. This is a large tree, with a ſhort trunk, and very long ſpreading boughs. Leaves ſmooth, of a light green, ſix or ſeven inches long, and three inches and a half broad towards the baſe, diminiſhing gradually to the top, where they run out into a narrow point, an inch and half long. The fruit comes out on the branches, is ſmall, and of no value; [According to Gærtner, it is the ſize of a ſmall hazel nut, ſlightly turbinate, (yellow, dotted;) when dry becoming thin, the ſubſtance of paper, of a dun colour, defended at the baſe with a one-leafed floral bracte repandly lobed; and having at the top three minute converging ſcalelets, cloſing the aperture there. The internal cavity is filled with flowers. The female flowers are trifid, and of a blackiſh brown colour. The ſeeds are ſmall, globular, whitiſh, ſmooth, cruſtaceous, fixed by a long, capillary, umbilical chord.—According to Linnæus it is the ſhape and ſize of peas, axillary, ſolitary, or aggregate. Calyx inferior, three-leaved'.

Native of the Eaſt-Indies and Cochinchina.—Cultivated in 1731, by Mr. Miller'.

5. This is a middle-ſized tree. Branches ſlender, flexuoſe, ſtreaked and wrinkled. Leaves petioled, exactly ovate, entire, very ſlenderly ſtreaked acroſs, with the edge diſtinct and ſmooth, perennial, and like thoſe of the pear; on very ſhort ſubulated petioles. Fruits globular, ſcattered on the branchlets. Native of the Eaſt-Indies'. Cultivated in 1757, by Mr. Miller'.

6. Stem ſhrubby, round, upright, all ſmooth, a fathom in height. Branches like the ſtem. Leaves ſomewhat waved, nerved, the ſize of the hand; on a ſemicylindric petiole, half an inch in length'.

Native of the Eaſt-Indies, and cultivated 1692, in the Royal Garden at Hampton Court.

7. Native of South America. Introduced 1736, by Hugh Duke of Northumberland.

8. Native of the Eaſt Indies. Introduced 1778, by Mr. William Malcolm'.

9. This vaſt tree is entirely ſmooth, the branches ſpreading very wide, bowed down, the lower ones rooting, aſh-coloured. Leaves acuminate, with a blunt point, obſcurely waved, marked with parallel nerves, paler underneath, a ſpan long, on ſemicylindric, aſh coloured petioles, of a finger's length. Fruits aggregate here and there on the branches, pedunckled, the ſize of a hazel nut'.

[1] Haſſelquiſt. [2] Gerard's herbal. [3] Hort. kew. [4] Linn. mant. [5] Hort. kew. [6] Linn. mant. [7] Hort. kew. [8] Linn. mant. & Thunb. cens. [9] Hort. kew. [10] Thunb. cens. [11] Hort. kew. [12] Thunb.

It is called by the Engliſh Banyan tree, and *arbor de Rayz*, that is, the rooting tree, by the Portugueze; and it propagates itſelf, as Mr. Evelyn obſerves, into a foreſt, by letting a kind of gummy ſtring fall from its branches, which takes root, and thus ſpreads a vaſt circuit. This, however, is the caſe with the third, fourth, fifth, ſixth and tenth ſpecies, and perhaps others.—One of theſe growing near Mangee, twenty miles weſt of Patna in Bengal, was in diameter 370 feet; the circumference of the ſhadow at noon was 1116 feet; the circumference of the ſeveral ſtems, which were fifty or ſixty in number, 921 feet[a].

There is a vaſt tree of this kind near Fort St. David's in the Eaſt-Indies, which is computed to cover near 1700 ſquare yards. A very celebrated Banian tree is alſo growing near Gombroon on the Perſian Gulph.

The Gentoos are almoſt as ſenſibly hurt, if any one cuts or lops off any of the branches, as if he had mutilated or deſtroyed a cow, which he holds in ſo much veneration[b].

Hence another ſpecies is named by Linneus *religioſa*, being ſacred to the idol *Viſhnu*, who is ſaid to have been born under it[c].

From the manner of its growth, Geſnerde names it the arched Indian Fig-tree.

Strabo mentions this tree, and ſays that the branches grow horizontally about twelve cubits, then taking a direction to the earth, where they root themſelves, and when they have attained maturity, continue to propagate in the ſame manner, till the whole becomes like a tent ſupported by many columns.

Pliny (l. 12. c. 5. (deſcribes this ſingular tree with his uſual elegance.—"Ficus ibi [in India] "exilia poma habet: ipſa ſe ſemper ſerens, vaſtis "diffunditur ramis, quorum imi adeo in terram "curvantur, ut annuo ſpatio infigantur, novamque "ſibi propaginem faciant circa parentem in orbem "quodam opere topiario. Intra ſepem eam æſti- "vant paſtores, opacam pariter & munitam vallo "arboris, decora ſpecie ſubter intuenti, proculve, "fornicato ambitu. Superiores ejus rami in excel- "ſum emicant, ſylvoſa multitudine, vaſto matris "corpore ut LX. paſſus plerique orbe colligant, "umbra vera bina ſtadia operiant."

Milton ſeems to have had theſe claſſical deſcriptions in his eye:—

> "Branching ſo broad and long, that in the ground
> "The bending twigs take root; and daughters grow
> "About the mother tree; a pillared ſhade,
> "High over-arched, with echoing walks between.
> "There oft the Indian herdſman, ſhunning heat,
> "Shelters in cool; and tends his paſturing herds
> "At loop-holes cut through thickeſt ſhade."

Native of the Eaſt-Indies and Cochinchina. Cultivated in 1759, by Mr. Miller[d].]

10. This riſes to the height of thirty or forty feet, ſending out many ſlender branches, which put out roots. Leaves eight or nine inches long, and two inches broad.

[The fruit is not bigger than a hazel-nut, of a ſcarlet or carnation colour, the taſte ſweetiſh, and not unpleaſant. It is much coveted by the Wild Pigeons[e].

Native of the Weſt-Indies. Introduced about 1762, by Mr. James Gordon.

11. 12. Natives of the Eaſt-Indies. Introduced in 1763, by Mr. John Buſh[f].

13. Branches round, ſmooth, ferruginous, upright; branchlets ſcattered, ſhort. Leaves oblong, nerved, ſmooth, pale underneath, from an inch to three inches and more in length, on round, grooved petioles, from half an inch to an inch long. Fruits in racemes, globular, almoſt the ſize of a plum[g].

Native of the Eaſt-Indies. Cultivated in 1759, By Mr. Millar[h].

14. A ſmall tree, with ſtriated ſpreading branches. Leaves acuminate, ovate oblong, entire, very ſmooth, with parallel nerves, on round, grooved petioles. Fruit red, the ſize of red currants, ſcattered in racemes, very abundant, pedicelled[i].

Native of South America. Introduced about 1780[k].

15. Leaves petioled, leathery, ſmooth and even, quite entire. Fruits on the branches, diſperſed; with a three-leaved, approximating calyx. Native of the Eaſt-Indies[l].

16. Stem creeping, rooting, round, full of chinks, aſh-coloured, ſmooth. Branches few, like the ſtem. Leaves entire, coriaceous, paler beneath, petioled. The ſmall branches at the leaves ſurrounded with an elevated ſtreak. Peduncles axillary, filiform, ſolitary. Calyx inferior, three-leaved. Fruits ovate, ſmooth, the ſize of a palm.—Native of China and Japan[m].

17. A middle ſized ſhrub, with round, ſmooth, ferruginous branches. Leaves acute, ſinuate-angular, gaſh-lobed, villoſe above, white-tomentoſe underneath, a ſpan and more in length, on round, ſtriated, ſubtomentoſe petioles. Fruits ovate, tomentoſe, the ſize of a plum, on thick, tomentoſe peduncles[n].

This is ſaid to be extremely poiſonous. It grows near Padan in Sumatra[o].

18. A middle-ſized tree, with upright ſtem and branches. Leaves large, rough, alternate petioled. Fruit middle-ſized, turbinate, brown, axillary, ſolitary[p].

Native of America. According to Thunberg the maculata and hiſpida of Syſt. veget. are one and the ſame plant.

19. This is a tree leafy at top, with round wrinkled tomentoſe branches, and very ſhort branchlets. Leaves petioled, ſcarcely cordate, acute, ſpreading, entire, more ribbed underneath, ſmooth. Fruits axillary, alternate, many, globular, the ſize of currants. Peduncles very ſhort, one-flowered. Calyx obtuſe. Navel triangular, each angle cleft with an oblong ſlit.—Native of Surinam[q].

20. The whole clothed with very minute thinly ſcattered hairs. Branches *round*, ſtriated, aſh-coloured, ſmooth. Leaves cuſped, ſerrate, rugged on both ſides, with hairy nerves, about a ſpan in length, on grooved petioles an inch long. Peduncle in the axil of the leaves, filiform, hiſpid with ſhort, rigid, yelloviſh, ſhining briſtles. Fruit globular, clothed with the ſame tegument as the peduncle[r], axillary, racemed, turbinate, the ſize of a plum, according to Thunberg.—Native of Java.

21. Stem filiform, decumbent, ruſeſcent, ſmooth; branches filiform, decumbent, bent in, ſtipuled, ruſeſcent. Stipules ſcattered, awl-ſhaped, ſpreading, ruſeſcent. Leaves entire, bright-green above, paler underneath and netted, on petioles ſcarcely half a line in length[s].

Native of China and Japan. Introduced about 1771[t].

22. Stem ſlender, ſubflexuoſe. Leaves petioled, with both ſurfaces very ſcabrous; the lower ones undivided, oblong, entire; the upper ones divided as in the common Fig[u].

It is thus deſcribed by Thunberg. Stem ſhrubby, erect, entirely rugged. Branches round, flexuoſe, elongated, little ſubdivided. Leaves cuſped, toothed, with a reflex margin, pale underneath, rugged on both ſides, nerved, from erect ſpreading, a finger's length, on ſemicylindric petioles. Fruits axillary, ovate, obtuſe, hiſpid, the ſize of a hazel nut, on peduncles ſhorter than the petioles. In Linneus's ſupplement they are deſcribed as ſmooth. Native of the Eaſt-Indies, near rivulets and watery places, ſcarcely acceſſible on account of the Rattans.—Cultivated in 1758, by Mr. Miller[x].

[a] Marſden's Sumatra, 130. [b] Ives's voy. to India, 199 & 460. [c] Hort. Malab. 1. 48. [d] Hort. kew. [e] Sloane. [f] Hort. kew. [g] Thunberg. [h] Hort. kew. [i] Linn. ſuppl. & Thunb. [k] Hort. kew. [l] Linn. ſyſt. & Thunb. [m] Thunberg. [n] Linn. [o] Loureiro. [p] Linn. ſuppl. & Thunb. [q] Linn. ſuppl. [r] Thunberg. [s] Horr. kew. [t] Linn. ſuppl. [u] Horr. kew. [x] Linn. mant.

23. Native of Java[1]. The ſame with F. benjamina, n. 5. according to Thunberg.

24. Native of the Eaſt-Indies. Introduced in 1772, by Mr. William Malcolm[2].

25. Native of the iſles of Tanna and Namoka in the South Seas[3].

26. This is a tree four or five fathoms in height, with jointed branches. Leave alternate, ſubpetioled, ovate-cordate, acuminate, the inner diſk narrower, hairy, ſpreading, a ſpan long. Petioles round, with a groove on the upper ſide. Receptacles (or fruit) axillary, in pairs, ſeſſile, ſilky-tomentoſe on the outſide, white, the ſize of the common Fig, fleſhy, juicy and inſipid. It has no common calyx, but an obſcure rim, entire, ſcarcely two or three-toothed, ſurrounds the receptacle where it begins to ſpread out[4].—Thunberg ſays that the fruit is globular, and the ſize of a plum.

Native of the iſle of Tanna[5] where it is alſo cultivated for the fruit, which is ſweet and pleaſant; the young leaves boiled are eaten as greens.

27. Native of the Society iſles[6].

28. Native of the iſle of Tanoa. In Otaheite it is called *Matte*.

Loureiro has given the ſame name to a Cochinchineſe Fig, on account of its ſeptic qualities. It is uſed there for eating off proud fleſh, and againſt worms. He deſcribes it, as a ſhrub eight feet high, and upright, with ſpreading branches. Leaves broad-lanceolate, quite entire, rough, ſcattered, petioled. Fruit oblong-turbinate, wrinkled, flaccid, lateral, axillary, on ſhort ſimple ſolitary peduncles, green, tinged with red. He refers to *Rumphius, t. 96.* and to *Burm. ind.* 226.

29. This is a tall ſhady tree, with a multangular toroſe trunk: all the branches aſcending, long, roundiſh, ſomewhat jointed, brown-aſh-coloured, unequal; branchlets round, jointed, leafy only at the end. Leaves crowded, alternate, ſmooth, with few yellow veins, dark green above, more ſhining beneath, a ſpan or more in length, ſpreading. Petioles roundiſh, ſmooth, ſpreading, one quarter of the length of the leaves. Terminating buds cloſer, like a ſpine, covered entirely with bay-coloured hairs. Peduncles from the axils of the upper leaf and the next, thick, very ſhort, round. Receptacle (or fruit) larger than the common Fig, ſubpubeſcent, roſe coloured with yellow ſpots, within purple, ſoft and pulpy. Common calyx three-leaved, with ſmall ovate-roundiſh leaflets. Cultivated (with the 26th) in the iſle of Tanna for its fruit, which is ſweetiſh, watery, and almoſt inſipid.

30. Native of the iſles of Namoka and Tanna.

31. Native of the Society iſles[7].]

32. This riſes with many ſhrubby ſtalks to the height of twelve or fourteen feet, and divides into many ſmaller branches. The leaves are four inches long, and three broad, of a light green, and ſtand upon very ſhort foot-ſtalks, joined to a cup in which the fruit ſits; this is globular, and the ſize of a middling nutmeg, of a deep yellow, when ripe, but is not eatable. Native of La Vera Cruz, whence it was ſent to Mr. Miller by Dr. Houſtoun.

33. The fruit is of a pale yellow colour, and ſpherical. Native of Jamaica.

[34. Stem weak, round, ſtriated and chinky, ferruginous aſh-coloured, ſmooth. Branches alternate or ſubumbelled-aggregate, like the ſtem. Leaves obovate, a little attenuated to both ends, entire, aſh-coloured and netted beneath, ſpreading, from an inch to a finger's length. Petioles ſubtrigonal, grooved, half an inch in length. Fruits ſcattered on the branchlets, erect, ſubglobular, the ſize of a hazel nut. It differs from F. pumila, of which it was ſuppoſed to be only a variety, in having larger leaves, leſs netted, and thinner; and ſmaller, ſweeter, more eatable fruits. Native of Japan[8].

35. Stem filiform, ruſeſcent, ſmooth. Branches alſo filiform, decumbent, bent in, ſtipuled, ruſeſcent. Stipules ſcattered, awl-ſhaped, ſpreading, ruſeſcent. Leaves entire, paler underneath and netted, on petioles ſcarcely half a line in length. Native of Japan[9].

36. This is a large tree, with oblique branches. Leaves ſubſerrate, tomentoſe, large, ſcattered, petioled. Fruit turbinate, two inches long, of an even ſurface, red within and without, in heaped, erect, terminating racemes. Calyxes of the receptacle three-leaved, permanent. Beſides the aperture at the top common to the whole genus, there are four diſtant holes on the ſhoulder of the fruit, leaved round by prominent cartilages reſembling ears.

Native of Cochinchina, where the fruit before it is ripe cut in ſlices laſtra like the cucumber, and is eaten in ſalads.

Capriſicus amboinenſis eſculenta of Rumphius agrees with the above in many circumſtances; but the fruit is ſmaller, lateral, and has no ears.

37. This is a ſhrub, ſix feet high, upright and branched. Leaves ſubacute, ſmall, petioled, ſcattered. Fruit very ſmall, ſaffron-coloured. Native of Cochinchina; where the dried leaves are uſed in poliſhing ſmall works in wood or ivory.

38. This is a ſhrub five feet in height, with an upright ſtraight ſtem, without any branches. Leaves rough, large, petioled, ſcattered. Fruit ſpheroidal, ſaffron-coloured, ſmall ſeſſile, axillary, ſolitary. Native of Cochinchina.

39. This is a ſhrub ſix feet in height, with a branching ſtem, covered with a ſmooth bark like hemp. All the leaves are very rough, petioled and ſcattered. Fruit oval-turbinate, on long, ſimple, ſolitary, lateral peduncles. Calyx trifid, with rounded ſegments.

Native of Cochinchina.

F. heterophylla of Koenig (n. 22.) does not agree with this in the leaves, nor in its ſeſſile, bifid ſtalk. Capriſicus chartaria of Rumphius approaches to this, eſpecially in its tough bark, which may be made uſe of for cloth, that ſerves many of the inhabitants of the iſlands in the South Seas for clothing[10]. See n. 84.

40. Branches round, ſmooth, with a wrinkled bark. Leaves quite entire, very ſmooth on both ſides, veined, two inches long, and of the ſame breadth at the baſe. Petiole the length of the leaf, and ſmooth. Peduncles in pairs, axillary, ſmooth, thicker at both ends, half an inch long; under the fruit two or three ſhort roundiſh ſcales. Fruit globular, ſmooth, the ſize of peas.

It is diſtinct from F. religioſa in having acute leaves, not ending in a long point, and peduncled fruits:—from nymphæifolia in the leaves being exquiſitely cordate, of the ſame colour on both ſides, by no means obtuſe and mucronate:—from Sycomorus and cordifolia of Thunberg in having the fruit peduncled.

Its proper place is between the third and fourth ſpecies.

41. Branches round, villoſe, tomentoſe towards the top. Leaves obtuſe, a little narrower at the baſe, with a narrow ſinus at the petiole, the upper ſurface even, the lower veined and ſoftiſh; they are two inches long, and have a villoſe petiole ſhorter than the leaf. Fruit ſolitary, ſmall.

Native of the Eaſt-Indies. Its proper place is between the fifth and ſixth ſpecies.

42. The whole of this is very ſmooth and even. Leaves pale-coloured, acuminate, rounded at the baſe, from three to five inches in length. Petioles an inch and half long. Stipules lanceolate, deciduous. Fruit globular, even, the ſize of peas. F. indica differs in having oblong leaves with an obtuſe point, fruits on the branchlets aggregate, and the ſize of a hazel nut, and the branches rooting. The place of this is between the fifth and ſeventh ſpecies.

43. Stem ſmooth, pubeſcent at top, and creeping by means of fibres oppoſite to the leaves; which

[7] Thunberg.
[8] Thunberg.
[9] Thunberg.
[10] Loureiro.

are quite entire, rugged on both ſides, with ſcattered dots underneath, ſharp, and inch and half long, having ſtraight earlets. Petioles ſcarcely two lines in length. Stipules lanceolate at both ends. Native of the Eaſt-Indies. The proper place is between the eleventh and twelfth ſpecies.

44. Branches angular at top, and hairy. Leaves two or three lobed at the top, very rugged on both ſides, veined, acute, remotely and unequally toothed, quite entire towards the baſe, and frequently on one ſide almoſt to the middle, two inches long and more, on a very ſhort, villoſe petiole. Fruit ſmooth, a little larger than a pea, terminated by a truncated wart, and roughened by unequal ſcattered tubercles. Native of the Eaſt-Indies.

This was ſent by Koenig under the name of F. heterophylla, but it is probably different from n. 22., ſince it does not agree in the ſize and form of the fruit; nor is it hiſpid, as Thunberg ſays the heterophylla is (p. 13.) See n. 39.

45 Branches angular, ſmooth and even. Leaves ſharp, netted-veined, ſhining above, paler underneath, two inches and more in length: lobes oblong, lateral, obtuſe. Petiole ſhort, wrinkled, channelled above. It differs from F. denticulata in having hairy branches, ſhorter petioles, leaves more tender and not at all ſhining, toothletted, and globular fruit, with larger and fewer dots. Native of the Eaſt-Indies.

46. Branches at top, and alſo the younger leaves, very rugged, with extremely ſmall and numerous dots. Leaves petioled, nerved, ſharp at the baſe, quite entire, opaque. Fruit almoſt the ſize of a hazel nut, villoſe, on a very ſhort peduncle.

This differs from the other ſpecies in having divided leaves, the branches and leaves dotted and rugged, the leaves palmate, repand at the baſe, narrowed, not rounded, and the fruit covered with very numerous minute dots.

47. Branches round, ſmooth. Leaves ſharply ſerrate, almoſt to the baſe, rugged on both ſides, veined, paler underneath, with purpliſh veins, two inches long: lobes ovate, acute. Petiole only half the length of the leaf. Frtuit ſolitary, a little larger than a pea. Peduncle the length of the fruit, with a pair of ſmall bractes on the middle of it. The proper place of the four laſt is between the ſixteenth and ſeventeenth ſpecies.—Perhaps not different from heterophylla [s].

48. This is a middle-ſized ſhrub, entirely ſmooth. Branches round, ſomewhat wrinkled, aſh-coloured, from erect ſpreading, branchletted. Leaves towards the ends of the branches and branchlets approximating, entire, netted-veined, ſpreading, an inch and half long, on round ſhort petioles. Fruits ſeſſile, towards the ends of the branches and branchlets in the axils of the leaves approximating, globular, the ſize of peas. Native of the Cape of Good Hope.

49. Stems filiform, decumbent, rooting, flexuoſe, brown. Branches filiform, ſimple, like the ſtem. Leaves obliquely inſerted, with one ſide narrower, blunt, very finely nerved, entire, pale underneath, on very ſhort petioles. Native of the Eaſt Indies.

50. Stem paraſitical, climbing, round, wrinkled, brown, ſcarcely the thickneſs of a gooſe quill. Branches flexuoſe, ſmooth, brown. Branchlets very ſhort. Leaves blunt, obſcurely emarginate, entire, with the edge a little bent back, ſmooth above, hollow-dotted underneath, ſpreading and reflex, from half an inch to an inch in length. Petioles very ſhort. Fruits obovate, nearly the ſize of the common Fig. Native of the Eaſt-Indies.

51. Stem entirely ſmooth. Branches ſtriated and wrinkled, from erect ſpreading. Leaves entire, marked with parallel nerves, ſpreading, from an inch to a hand in length, on ſemicylindric very ſhort petioles. Fruits at the ends of the branchlets, ſeſſile, globular, retuſe, the ſize of peas.

52. Branches ſtriated and wrinkled, reflex, aſh-coloured, ſmooth. Leaves entire, marked with parallel nerves, a finger's length, on aſh-coloured petioles ſhorter by half than the leaf. Fruits ſcattered, and aggregate on the branches, ſmooth, the ſize of peas. Native of the Eaſt-Indies.

53. Branches round, grooved, ſmooth. Leaves ſcattered, acuminate, coriaceous, entire, nerved, aſh-coloured underneath, the ſize of the hand, on ſemicylindric, thick, ſhort petioles. Fruits towards the ends of the branches, ſmooth, the ſize of plums. Native of the Eaſt-Indies.

54. Branches round, wrinkled, purple, ſmooth, upright. Leaves obovate, attenuated below, toothed and bent back at the edge, pale beneath, ſpreading, the ſize of the hand, on ſemicylindric, thick, very ſhort petioles. Fruits axillary, ſmooth, larger than peas, on peduncles a line in length. Native of the Eaſt-Indies.

55. Branches round, ſtriated, aſh-coloured, ſmooth, erect. Leaves tooth-angular at top, with a reflex margin, entire at bottom, pale underneath, nerved, netted, ſpreading, the ſize of the hand, on ſemicylindric, grooved, ſhort petioles. Fruits on the branchlets ſcattered and aggregate, ſeſſile, globular, ſomewhat knobbed, ſmooth, ſcarcely the ſize of pepper. Native of the Eaſt-Indies.

56. This is a vaſt lofty ſmooth tree, with ſpreading branches. Leaves ſinuate-toothed, paler underneath, nerved, ſpreading, a finger's length. Fruits ſcattered, turbinate, the ſize of a hazel nut, or bigger. Native of the Cape of Good Hope [t].]

PROPAGATION AND CULTURE.

1. The firſt, ſecond, third, ninth and tenth varieties will ripen their fruits on ſtandards, where they are in a warm ſituation; but the others require the aſſiſtance of walls expoſed to good aſpects, otherwiſe their fruit will not ripen in England.

Fig-trees generally thrive in all ſoils, and in every ſituation; but they produce a greater quantity of fruit upon a ſtrong loamy ſoil, than on dry ground; for if the ſeaſon proves dry in may and june, thoſe trees which grow upon very warm dry ground, are very ſubject to caſt their fruit; therefore whenever this happens, ſuch trees ſhould be well watered and mulched, which will prevent the fruit from dropping off; and the fruit upon theſe trees are better flavoured than any of thoſe which grow upon cold moiſt land. I have always obſerved thoſe Fig-trees to bear the greateſt quantity of well-flavoured fruit, which were growing upon chalky land, where there has been a foot or more of a gentle loamy ſoil on the top. They alſo love a free open air; for although they will ſhoot and thrive very well in cloſe places, yet they ſeldom produce any fruit in ſuch ſituations; and all thoſe which are planted in ſmall gardens in London, will be well furniſhed with leaves, but I have never ſeen any fruit upon them which have grown to maturity.

Theſe trees are always planted as ſtandards in all warm countries, but in England they are generally planted againſt walls, there being but few ſtandard Fig-trees at preſent in the Engliſh gardens; however, ſince ſome of the ſorts are found to ripen their fruit well upon the ſtandards, and the crop of Figs is often greater upon them than upon thoſe trees againſt walls, it is worthy of our care to plant them either in ſtandards or eſpaliers; the latter, I think, will ſucceed beſt in England, if they were managed as in Germany, where they untie the Fig-trees from the eſpalier, and lay them down, covering them in winter with ſtraw or litter, which prevents their ſhoots being injured by the froſt; and this covering is taken away gradually in the ſpring, and not wholly removed until all the danger of froſt is over, by which management they generally have a very great crop of Figs; whereas in England, where the trees grow againſt warm walls, if the ſpring proves warm, the young Figs are puſhed out early, and the cold, which frequently returns in april and may, cauſes the greateſt part of the fruit to drop off; ſo

[s] Vahl.

[t] Thunb. monogr.

tha-

that our crop of Figs is generally more uncertain than moſt other ſorts of fruit; and it frequently happens, that trees which are planted againſt north and eaſt-aſpected walls, produce a greater quantity of fruit in England than thoſe which are planted againſt ſouth and ſouth-eaſt aſpects; which muſt happen from the latter putting out their fruit ſo much earlier in the ſpring than the former: and if there happen cold froſty nights after the Figs are come out, which is frequently the caſe in this country, the forwardeſt of the Figs are generally ſo injured as to drop off from the trees ſoon after. In Italy, and the other warm countries, this firſt crop of Figs is little regarded, being few in number; for it is the ſecond crop of Figs produced from the ſhoots of the ſame year, which is their principal crop, but theſe rarely ripen in England; nor are there above three or four ſorts which ever ripen their ſecond crop, let the ſummer prove ever ſo good, therefore it is the firſt crop which we muſt attend to in England; ſo that when theſe trees are growing againſt the beſt aſpected walls, it will be a good method to looſen them from the wall in autumn; and after having diveſted the branches of all the later fruit, to lay the branches down from the wall, faſtening them together in ſmall bundles, ſo that they may be tied to ſtakes, to keep them from lying upon the ground; the damp whereof, when covered in froſty weather, might cauſe them to grow mouldy, and hereby they will be ſecured from being broken by the wind. When they are thus managed in autumn, if the winter ſhould prove very ſevere, the branches may be eaſily covered with peas-haulm, ſtraw, or any other light covering, which will guard the tender fruit-bearing branches from the injury of froſt; and when the weather is mild, the covering muſt be removed, otherwiſe the Figs will come out too early; for the intention of this management is to keep them as backward as poſſible; then in the ſpring, when the Figs are beginning to puſh out, the trees may be faſtened up to the wall again. By this management I have ſeen very great crops of Figs produced in two or three places.

I have alſo ſeen great crops of Figs in ſome particular gardens, after very ſharp winters, when they have, in general, failed in other places, by covering up the trees with Reeds made into pannels, and fixed up againſt the walls.

In pruning Fig-trees, the branches muſt never be ſhortened, becauſe the fruit is all produced at the upper part of the ſhoots of the former year; if theſe are cut off, there can be no fruit expected; beſides, the branches are very apt to die after the knife; ſo that when the branches are too cloſe together, the beſt way is to cut out all the naked branches quite to the bottom, leaving thoſe which are beſt furniſhed with lateral branches at a proper diſtance from each other, which ſhould not be nearer than a foot; and when they are well furniſhed with lateral-branches, if they are laid four or five inches farther aſunder, it will be better.

The beſt ſeaſon for pruning Fig-trees is in autumn, becauſe at that time the branches are not ſo full of ſap, and will not bleed ſo much as when they are pruned in the ſpring; and at this ſeaſon the branches ſhould be diveſted of all the autumnal Figs, and the ſooner this is done, when the leaves begin to fall off, the better will the young ſhoots reſiſt the cold of the winter. There are ſome ſeaſons ſo cold and moiſt, that the young ſhoots of the Fig-trees will not harden, but are ſoft, and full of juice; when this happens, there is little hope of a crop of Figs the ſucceeding year, for the firſt froſt in autumn will kill the upper part of theſe ſhoots for a conſiderable length downward; whenever this happens it is the beſt way to cut off all the decayed part of the ſhoots, which will prevent the infection from deſtroying all the lower part of the branches; and, by this method, I have ſeen a moderate crop of Figs put out from the lower part of the ſhoots; where, if the ſhoots had not been injured, there would have been no fruit produced, becauſe it is chiefly from the four or five uppermoſt joints of the ſhoots that the fruit comes out; and it is for this reaſon, that as many of the ſhort lateral branches ſhould be preſerved as poſſible, thoſe being the moſt productive of fruit; for where the long ſtraight ſhoots are faſtened up, there will be no fruit, but at their extremities, ſo that all the lower part of the trees will be naked, if there is not a particular regard had to ſupply young ſhoots in every part of the trees.

Thoſe trees which are laid down from the eſpaliers, ſhould not be faſtened up again till the end of march for the reaſons before given, and thoſe againſt walls may remain ſome time longer; and when the large ſhoots of theſe are nailed up, if the ſmall lateral branches are thruſt behind theſe, to keep them cloſe to the wall, it will ſecure the young Figs from being injured by the morning froſts; and when this danger is over, they may be brought forward to their natural poſition again; during the ſummer ſeaſon theſe trees will require no other pruning, but to ſtop the ſhoots in the ſpring, where lateral branches are wanting; and as the branches are often blown down by wind, therefore whenever this happens, they ſhould be immediately faſtened up again, otherwiſe they will be in danger of breaking; for the leaves of theſe trees being very large and ſtiff, the wind has great power on them: ſo that where the branches are not well ſecured, they are frequently torn down.

Thoſe trees which are planted againſt eſpaliers may be protected from the injury of froſt in the ſpring, by placing Reeds on each ſide the eſpalier, which may be taken down every day, and put up again at night; but this need not be practiſed in warm weather, but only at ſuch times as there are cold winds and froſty mornings; and although there is ſome trouble and expence attending this management, yet the plentiful crop of Figs which may this way be obtained, will ſufficiently recompenſe for both; the beſt way of making this covering is, to faſten the Reeds with rope-yarn in ſuch a manner as that they may be rolled up like a mat, that the whole may with great facility be put up or taken down; and if theſe Reeds are carefully rolled up, after the ſeaſon for uſing them is over, and put up in a dry ſhed, they will laſt ſeveral years.

There are ſeveral perſons who of late have planted Fig-trees in ſtandards, which have ſucceeded very well; this practice was revived, by obſerving ſome old ſtandard Fig-trees in ſome gardens, which had been growing many years, and generally produced a much greater plenty of fruit than any of thoſe trees which were growing againſt warm walls; indeed, theſe ſtandard Fig-trees are in much greater danger of having their branches killed by ſevere froſt, but in mild winters they generally do better than thoſe againſt walls; ſo that where theſe trees can be covered in very hard winters, there will always be plenty of fruit; and theſe may be covered by faſtening as many of the branches together as can be conveniently brought into a bundle, and winding ſome hay-bands, ſtraw, peas-haulm, or any ſuch light covering as can be readily procured, which in the ſpring may be gradually taken off, ſo as not to expoſe the ſhoots all at once to the open air; and if there is ſome ſuch light covering laid round the ſtems, and upon the ſurface of the ground about their roots, it will more effectually ſecure them from the danger of froſt; but when this is practiſed, great care ſhould be taken that no mice or rats harbour in this covering, for theſe will eat off the bark from their ſhoots, and kill them: and I have often obſerved thoſe trees which were againſt walls, have ſuffered greatly by theſe vermin, by having many of their largeſt branches diſbarked near the ground, which has abſolutely killed them; and it is in the winter that theſe vermin do this miſchief to them, therefore they ſhould be carefully watched at that ſeaſon.

The common blue and white Figs, which are the ſorts which have been the moſt generally cultivated in England, are not ſo proper to plant for ſtandards as ſome other ſorts which have been lately intro-

duced; for they are much tenderer, and are often killed almoſt to the root, when ſome of the other ſorts, which have been growing in the ſame ſituation, have received very little injury from the froſt; indeed the white ſort is generally a great bearer, and the fruit is very ſweet; but to thoſe palates which are accuſtomed to Figs, that ſort is not much in eſteem, from its want of flavour; thoſe which have ſucceeded beſt with me, are the firſt and third ſorts. Their branches are rarely hurt by froſt in winter, and their fruit will always ripen well; for in favourable ſeaſons, many of theſe ſorts, which were growing againſt walls, have ripened their ſecond crop of fruit tolerably well. I have alſo planted many of theſe ſorts of Fig-trees againſt north-eaſt and north-weſt aſpects; ſome of thoſe which were firſt planted, have produced a good quantity of well taſted fruit, but were ripe much later, which has encouraged me to plant many more of theſe trees to the ſame aſpects, and alſo to increaſe my number of ſtandard trees.

I am aware, that what I have here advanced, in relation to the pruning and dreſſing of Fig-trees, will be condemned by great numbers of people, who will not give themſelves time to conſider and examine the reaſons upon which I have founded this practice, nor to make one ſingle experiment to try the truth of it, as being vaſtly different from the general practice of moſt gardeners, who always imagine, that Fig-trees ſhould never have much pruning; or, at leaſt, that they ſhould always be ſuffered to grow very rude from the wall, to ſome diſtance. That by this management I have often ſeen great quantities of fruit I cannot deny, but then this has been only after mild winters; for it is very certain, that in ſharp froſts few of theſe outſide ſhoots eſcape being greatly injured where they are not covered; whereas it rarely happens that thoſe ſhoots which are cloſely nailed to the wall in autumn, or laid down and covered, ſuffer the leaſt damage; and the fruits are always produced a fortnight ſooner upon theſe branches, than they are upon thoſe which grow from the wall: but although the trees which are ſuffered to grow rude from the walls may produce a good quantity of fruit for a year or two, yet afterwards the trees will only bear at the ends of the ſhoots, which will then be ſo far from the wall, as to receive little benefit from it; nor can the trees be reduced again to any regularity, without cutting away the greateſt number of their branches, by which a year or two will be loſt before they will come to bear again.

The ſeaſon alſo for pruning, which I have laid down, being vaſtly different from the common practice and opinion of moſt gardeners, will alſo be objected againſt; but I am ſure, if any one will but make trial of it, I doubt not his experience will confirm what I have here advanced; for as one great injury to this tree proceeds from the too great effuſion of ſap at the wounded parts, by this autumn pruning this is prevented; for, at that ſeaſon, all the parts of European trees which caſt their leaves, are leſs replete with moiſture than at any other time of the year; for by the long continuance of the ſummer's heat, the juices of plants having been exhauſted in the nouriſhment and augmentation of wood, leaves, fruits, *&c.* and alſo great quantities being evaporated by perſpiration, the root not being able to ſend up a ſupply equivalent to this great conſumption, the branches muſt contain a much leſs quantity of ſap than in the ſpring, when it has had ſeveral months ſupply from the root; which, though but ſmall in proportion to what is ſent up when the heat is greater, yet there being little or no waſte, either by perſpiration or augmentation, there muſt be a greater quantity contained in the branches; which alſo is eaſily to be obſerved, by breaking or cutting off a vigorous branch of a Fig-tree at both ſeaſons, the ſap, being milky, may be readily diſcerned, when that cut in autumn ſhall be found to ſtop its bleeding in one day's time, or leſs; whereas that cut in the ſpring will often flow a week or more, and the wound will be proportionably longer before it heals.

Of late years ſome of theſe trees have been planted againſt fire-walls, which have ſucceeded very well where they have been properly managed; but where they have been kept too cloſe, and drawn by glaſſes, they have not produced much fruit; therefore whenever this is practiſed, the heat ſhould not be too great, nor the glaſſes, or other covering, kept too cloſe, but at all times, when the weather is favourable, a good ſhare of free air ſhould be admitted; and if the trees are young, that their roots are not extended beyond the reach of the covering, they muſt be frequently watered when they begin to ſhew fruit, otherwiſe it will drop off; but old trees, whoſe roots are extended to a great diſtance, will only require to have their branches now and then ſprinkled over with water. If theſe trees are properly managed, the firſt crop of fruit will be greater than upon thoſe which are expoſed to the open air, and will ripen ſix weeks or two months earlier, and a plentiful ſecond crop may alſo be obtained, which will ripen early in ſeptember, and ſometimes in auguſt, which is about the ſeaſon of their ripening in the warmer parts of Europe: but the fires ſhould not be uſed to theſe trees till the beginning of february: becauſe when they are forced too early, the weather is frequently too cold to admit a ſufficient quantity of freſh air to ſet the fruit; but the covers ſhould be put over the trees a month before, to prevent the ſhoots from being injured by the froſt.

It may not be improper in this place to mention the great pains which the inhabitants of the Levant are at in the culture of their Figs; and without which (it is generally ſaid by all travellers who have written on this ſubject, as alſo by Pliny, and other old naturaliſts) their fruit will fall off, and be good for nothing. I ſhall here ſet it down, as I find it in the travels of Monſ. Tournefort*.

" Pliny (ſays he) obſerved, That in Ceos now " Zia they uſed to dreſs the Fig-trees with much " care; they ſtill continue to do ſo. To under- " ſtand aright this huſbandry of Figs, called in " Latin Caprificatio, we are to obſerve, that in " moſt of the Iſlands of the Archipelago, they have " two ſorts of Fig-trees to manage: the firſt is " called Ornos, from the old Greek, Ernos, a wild " Fig-tree; or Caprificus, in Latin; the ſecond is " the domeſtic, or garden Fig-tree; the wild ſort " bears three kinds of fruit, Fornites, Cratitires, " and Orni, of abſolute neceſſity towards ripening " thoſe of the garden Fig.

" The Fornites appear in auguſt, and continue to " november, without ripening; in theſe breed ſmall " worms, which turn to a ſort of gnats, no where " to be ſeen but about theſe trees. In october and " november theſe gnats of themſelves make a punc- " ture into the ſecond fruit, which is called Crati- " tires; theſe do not ſhew themſelves till towards " the end of ſeptember; and the Fornites gradually " fall away after the gnats are gone; the Cratitires, " on the contrary, remain on the tree till may, and " incloſe the eggs depoſited by the Fornites, when " they pierced them. In may the third ſort of " fruit begins to put forth from the ſame wild Fig- " trees which produced the other two; theſe are " much bigger, and are called Orni; when they " grow to a certain ſize, and the bud begins to " open, they are pricked in that part by the gnats " of the Cratitires, which are in a proper ſtate to " go from one fruit to the other, to diſcharge their " eggs.

" It ſometimes happens, that the gnats of the " Cratitires are ſlow to come forth in certain places, " while the Orni in thoſe very places are diſpoſed " to receive them; in which caſe the huſbandman " is obliged to look for the Cratitires in another " place, and fix them at the end of the branches of " thoſe Fig-trees, whoſe Orni are in fit diſpoſition

* Letter 8.

" to be pierced by the gnats; if they miſs the op-
" portunity, the Orni fall, and the gnats of the Cra-
" titires fly away. None but thoſe that are well
" acquainted with this ſort of culture, know the
" critical minutes of doing this; and in order to it,
" their eye is perpetually fixed on the bud of the
" Fig; for that part not only indicates the time
" that the flies are to iſſue forth, but alſo when the
" Fig is to be ſucceſsfully pierced; if the bud be
" too hard, and too compact, the gnat cannot lay its
" eggs, and the Fig drops when this bud is too open.

" Theſe three ſorts of fruit are not good to eat;
" their office is to help to ripen the fruit of the gar-
" den Fig-trees, in manner following: during the
" months of june and july, the peaſants take the
" Orni at a time that their gnats are ready to break
" out, and carry them to the garden Fig-trees; if
" they do not nick the moment, the Orni fall, and
" the fruit of the domeſtic or garden Fig-tree not
" ripening, will, in a very little time, fall in like
" manner. The peaſants are ſo well acquainted
" with theſe precious moments, that every morn-
" ing, in making their inſpection, they only transfer
" to their garden Fig-trees ſuch Orni as are well
" conditioned, otherwiſe they loſe their crop. It
" is true, they have one remedy, though an indiff-
" ferent one, which is, to ſtrew over the garden Fig-
" trees the Aſcolimbros, a very common plant there,
" and in whoſe fruit there is a ſort of gnats proper
" for piercing, perhaps they are the gnats of the
" Orni, which are uſed to hover about and plunder
" the flowers of this plant.

" In ſhort, the peaſants ſo well order the Orni,
" that their gnats cauſe the fruit of the garden Fig-
" tree to ripen in the compaſs of forty days. Theſe
" Figs are very good freſh; when they would dry
" them, they lay them in the ſun for ſome time,
" then put them in an oven to keep them the reſt
" of the year. Barley bread and dried figs are the
" principal ſubſtance of the peaſants and monks
" of the Archipelago; but theſe Figs are very far
" from being ſo good as thoſe dried in Provence,
" Italy, and Spain; the heat of the oven deſtroys
" all their delicacy and good taſte; but then, on the
" other hand, this heat kills the eggs which the
" flies of the Orni diſcharged therein, which eggs
" would infallibly produce ſmall worms that would
" prejudice theſe fruits.

" What an expence of time and pains is here for
" a Fig, and that but an indifferent one at laſt! I
" could not ſufficiently admire the patience of the
" Greeks, buſied above two months in carrying
" theſe flies from one tree to another. I was ſoon
" told the reaſon, one of their Fig-trees uſually
" produces between two and three hundred pounds
" of Figs, and ours in Provence ſeldom above
" twenty-five.

" The flies contribute, perhaps, to the maturity
" of the fruit of the garden Fig-tree, by tearing
" the veſſels in depoſiting their eggs; and thus
" cauſing the nutritious juice to extravaſate; per-
" haps too, beſide their eggs, they leave behind them
" ſome ſort of liquor proper to ferment gently with
" the milk of the Fig, and to make their fleſh
" tender."

[Monſieur Juſſieu doubts whether the ſucculency and turgeſcence of the eſculent Fig be owing to the defluxion of the nutritious juice occaſioned by the punctures of the inſects; or to the impregnation of the ſeeds from the farina conveyed by them. The ſexual botaniſts have adopted the latter cauſe, and regard it as one main prop of their ſyſtem. Here, as in ſimilar caſes, two purpoſes are anſwered at once, the impregnation of the ſeed, and the ripening of the pulp.]

" Our Figs in Provence, and even at Paris, ripen
" much ſooner for having their eyes pricked with a
" ſtraw dipped in olive oil. Plums and Pears,
" pricked by ſome inſects likewiſe ripen much the
" faſter for it; and the fleſh round ſuch puncture
" is better taſted than the reſt. It is not to be
" diſputed but that conſiderable change happens to
" the contexture of fruits ſo pricked, juſt the ſame
" as to parts of animals pierced with any ſharp in-
" ſtrument.

" It is ſcarce poſſible well to underſtand the an-
" cient authors who have treated of caprification,
" or huſbanding and dreſſing the wild Fig-tree,
" without being well apprized of theſe circum-
" ſtances, the particulars whereof were confirmed to
" us not only at Zia, Tinos, Micone, and Scio, but
" in moſt of the other iſlands."

Fig-trees are propagated in England, either by the ſuckers, which are ſent out from their roots, or by layers made by laying down their branches, which in one year will put out roots ſufficient to be removed, or by planting cuttings, which if properly managed, will take root; the firſt of theſe is a bad method, becauſe all thoſe trees which are raiſed from ſuckers, are very ſubject to ſend out great quantities of ſuckers again from their roots; and the branches of the ſuckers are not ſo compact, as thoſe of the layers, but are fuller of ſap, and in greater danger of being injured by the froſt; thoſe plants which are propagated by layers are the beſt, provided the layers are made from the branches of fruitful trees: for thoſe which are made from the ſuckers, or ſhoots, produced from old ſtools, being very ſoft, and full of ſap, are in danger of ſuffering by the froſt, and theſe will ſhoot greatly into wood, but will not be very fruitful; for, when trees have acquired a vicious habit while young, it is ſeldom they are ever brought to be fruitful afterwards; therefore the ſhoots which are laid down, ſhould be ſuch as are woody, compact, and well ripened, not young ſhoots, full of ſap, whoſe veſſels are large and open.

The beſt time for laying down the branches is in autumn; and if the winter ſhould prove very ſevere, if they are covered with ſome old tan, or any other mulch, to keep the froſt from penetrating the ground, it will be of great ſervice to them; by the autumn following, theſe will be ſufficiently rooted for removing, when they ſhould be cut off from the old plants, becauſe at that ſeaſon the branches not being ſo full of ſap as in the ſpring, will not bleed ſo much as when cut off at that ſeaſon. If the place is ready to receive them, the layers ſhould be tranſplanted in autumn, where they are to remain; but if it is not, then the layers may remain till the ſpring, provided they are ſeparated from the old plants in autumn. As theſe plants do not bear tranſplanting well when they are large, it is the better way to plant them at firſt in places where they are to remain; and after they are planted, the ſurface of the ground about their roots ſhould be covered with mulch to keep out the froſt; and if the winter ſhould prove very ſevere, it will be proper to cover the branches with Reeds, Peas-haulm, Straw, or ſome other light covering, which will prevent their tender ends being killed by the froſt, which frequently happens where this care is wanting.

The other method of propagating theſe trees, is by cuttings, which ſhould be taken from the trees in autumn, for the reaſon before given; theſe muſt be choſen from ſuch branches as are compact, whoſe joints are near each other; and they ſhould have a part of the former year's wood at their bottom, and the top of each ſhould be left entire, not ſhortened as is uſually practiſed with other cuttings; then they ſhould be planted eight or nine inches deep, in a bed of loamy earth, in a warm ſituation, covering the ſurface of the ground, three or four inches thick, with old tanner's bark, to keep out the froſt; and in ſevere froſt, their tops ſhould be covered with Straw, Peas-haulm, Fern, or other light covering, to protect them from froſt, theſe ſhould be removed in the ſpring; but the tan may remain, for that will prevent the drying winds of the ſpring, and the ſun in ſummer, from penetrating the ground, and will be of great uſe to ſecure the cuttings from injury; theſe cuttings will be rooted ſufficiently by the following autumn, when they ſhould be

tranſ-

tranſplanted, and treated in the ſame manner as the layers.

If fruitful branches of theſe trees are cut off, and planted in pots, or tubs, filled with good earth, and theſe are plunged into a good hot-bed of tanner's bark in the ſtove, they will put out fruit early in the ſpring, which will ripen in the middle of may.

2. &c. The other ſorts are preſerved in ſeveral curious gardens; they are eaſily propagated by cuttings during the ſummer ſeaſon. When the cuttings are taken from the plants, they ſhould be laid in a dry ſhady place for two or three days, that the wounds may be healed over, otherwiſe they are apt to rot; for all theſe plants abound with a milky juice, which flows out whenever they are wounded; for which reaſon, the cuttings ſhould have their wounded part healed over and hardened before they are planted; after which they ſhould be planted in pots filled with ſandy light earth, and plunged into a moderate hot-bed, where they ſhould be ſhaded from the ſun, and two or three times a week gently refreſhed with water, if the ſeaſon is warm; but they muſt not have too much moiſture, for that will infallibly deſtroy them. When the cuttings have taken root ſufficient to tranſplant, they ſhould be each planted into a ſeparate ſmall pot filled with light undunged earth, and plunged into the hot-bed again, being careful to ſhade them until they have taken freſh root; then they ſhould have a large ſhare of free air admitted to them at all times when the weather is favourable, to prevent their drawing up weak, and to give them ſtrength before the cold comes on. In autumn the pots ſhould be removed into the ſtove, and plunged into the tan-bed, where they ſhould conſtantly remain, and muſt be treated in the ſame manner as other tender plants from the ſame countries; for although two or three of the ſorts may be treated in a hardier manner, yet they will not make much progreſs.

Nat. order of *Compoſitæ Nucamentaceæ.—Corymbiferæ* Juſſ.

GENERIC CHARACTER.

CAL. *Common* of imbricate chaffs, containing in the *diſk* ſeveral hermaphrodite florets; in the *circumference* among the lower ſcales of the calyx ſolitary female florets.

COR. *Hermaphrodite* funnel-form, with a four-cleft erect border. *Females* ſcarcely viſible, filiform, very narrow, cloven at the mouth.

STAM. in the hermaphrodite. *Filaments* four, capillary, ſmall. *Anthers* cylindric, four-toothed at the top.

PIST. in the hermaphrodite. *Germ* ſcarcely any. *Style* ſimple. *Stigma* acute, bifid.—In the females *germ* ovate, largiſh, depreſſed. *Style* filiform. *Stigma* acute bifid.

PER. none.

SEEDS in the hermaphrodites none.—In the females obovate, compreſſed, ſmooth, ſmall. *Down* none.

REC. Diſk naked without chaffs, but at the ſides there are calycine chaffs ſeparating the florets.

OBS. *The above character is taken from* F. pygmæa *or* acaulis, *which Gærtner ſeparates under the name of* Evax:—F. germanica, arvenſis, montana, *and probably other ſpecies agree together, and are diſtinguiſhed from that by the following character.*

CAL. *Common* round or five-cornered, imbricate: *ſcales* ovate-lanceolate; the outer acute, tomentoſe, the inner ſhining, coloured, acuminate.

COR. *Compound: corollets* hermaphr. tubular few in the centre of the diſk: *females* tubular numerous in the remainder of the diſk; and a few others, almoſt apetalous among the outer ſcales of the calyx.

Proper in the hermaphrodites funnel-form, with a four-cleft ſpreading border:—in the females of the diſk funnel-form, with a ſlender tube ſwelling at the baſe, and a four-cleft erect border:—in the other females hardly conſpicuous, with a very ſlender tube, and a ſharp cloven border.

STAM. in the hermaphr. *Filaments* four very ſhort. *Anther* tubular.

PIST. in the hermaphr. *Germ* ſmall abortive. *Style* capillary, the length of the border. *Stigmas* two, from upright ſpreading.

Females in the diſk have an oblong *germ*; a capillary *ſtyle* longer than the border, and two ſpreading *ſtigmas*.

Females within the calyx have an oblong *germ*; a capillary *ſtyle* longer than the border, and two long ſpreading *ſtigmas*.

PER. none. *Calyx* unchanged.

SEEDS in the *hermaphrodites* barren, crowned with down:—in the *females* of the diſk oblong, crowned with a ſhort ſimple *down*:—in the *females* within the calyx oblong naked.

REC. naked*.

ESSENTIAL CHARACTER.

Cal. imbricate. *Female florets* among the ſcales of the calyx. *Down* none. *Recept* naked.

Stem very ſimple, head of flowers terminating radiated with very hirſute bractes.

DESCRIPTIONS, *&c.*

The Cudweeds are herbs covered with a hoary or cottony down. The flowers are uſually glomerate at the end of the ſtalk, and are ſometimes ſurrounded by a leafy ring. They are of the ſame natural genus with *Gnaphalium*, and are joined with it by Scopoli, *&c.* The firſt differs from the reſt in the ſhape of the receptacle, in having very few androgynous florets and all the ſeeds bald or naked.

1. A very ſmall plant, covered entirely with a white woolly nap, growing in a tuft. It has a little briſtle-form ſtem, a line or two, ſometimes half an inch, or at moſt an inch in height, erect, quite ſimple. Leaves moſtly cloſe to the ground, longer than the ſtem and flowers, quite entire, linear. One or two flowers terminate the ſtem, or are ſeſſile among the leaves. Calyx ſcarcely a line in length; the ſcales brown or reddiſh brown about the edge, aſh-coloured in the middle: the corollets are roſe-coloured, and the central ones yelloviſh [a].

According to Allioni, the ſeeds are crowned with a little membrane, and not with a *pappus* or down; and the receptacle is ſcaly.—Linneus affirms that it very ſeldom ſhoots up into ſtalk; and that the flowers are ſeſſile cloſe to the ground within a ring of leaves [b].

[a] Krocker. [b] Linn. ſyſt.

Cavanilles, with a zeal truly laudable, has defended Linneus from the intemperate and ill-founded attack of Monſ. Lamarck upon him reſpecting this plant, and has retorted it upon the aſſailant. He informs us that he has found cauleſcent plants about Madrid, accompanied by innumerable others abſolutely ſtemleſs, both flowering, fruiting and periſhing without any change from one to the other. In the latter caſe, the leaves are numerous, linear ovate, ſpread out in form of a roſe on the ground, the outer ones longer, the whole diameter an inch and half; from ſix to nine flowers are placed in the centre or near it, without any certain order. In the former caſe, there is ſometimes one ſtem, ſometimes ſeveral, and thoſe even branched; ſtem-leaves ſeſſile, numerous, ſublinear, broader at the end and blunt, thoſe which ſurround the flowers are in form of a roſe and larger, being a ſort of involucre; very frequently the ſtem at top is divided into a ſort of corymb, of unequal branchlets from ſix to nine, never ſo long as an inch. Calycine ſcales pellucid, ſmooth, with a divaricating briſtle at top: hermaphrodite florets five (ſeven to ten, *G.*) barren, naked, five parted (four-toothed, *G.*); ſegments reflex, acute; in the females none. Receptacle acutely conical, naked (chaffy, *G.*) Down none.

Krocker and Cavanilles have given two figures of it, one in its ſeſſile, and another in its cauleſcent ſtate.

Native of the South of Europe, and of the Levant, in dried pools of water. Annual. Flowering at the end of ſummer.

2. Root annual, ſpindle-ſhaped. Several ſtems riſe immediately from the root, from ſix to twelve inches in height, the central one thickeſt and longeſt, cloathed with numerous, linear-lanceolate, waved, ſeſſile, downy leaves. At the ſummit a ſeſſile flowering head, beneath which are two or more branches bearing flowers, and theſe again proliferous [c]. The lower lateral branches overtopping the principa central head, gave occaſion to the old name of *Herba impia.*

Calyxes pyramidal, five-cornered, ſcales ſharp, ſhining, brown with yelloviſh edges [d]. Florets of three ſorts: 1. Two or three in the centre hermaphrodite; the border four-cleft, ſpreading; ſtigmas from erect patulous, the length of the border; germ ſmall, abortive, with a ſhort ſimple down. 2. On the ſides of the diſk numerous, female; tube ſlender ſwelling at the baſe; border four-cleft, erect; ſtigmas patulous, longer than the border; ſeed fertile, with a down like the other. 3. Between the ſcales of the calyx, five or ſeven, female; tube ſcarcely viſible with a glaſs; border bifid, ſharp; ſtyle longer than the border, with long, ſpreading ſtigmas; ſeed oblong, fertile, without any down [e].

The deſcription of Dr. Stokes differs in ſome points.—Flowers conical, ſeſſile, yelloviſh brown. Heads ſolitary, ſurrounded with ſcattered leaves. Filaments four; anthers with two briſtles at the baſe, as in *Inula.* Seeds in the diſk oblong, compreſſed, greeniſh brown, beſet with white pellucid glands, crowned with down; thoſe between the outer ſcales of the calyx abortive.—Dr. Withering adds, that the germs in all the florets are rough and have a down.

According to Gærtner, he receptacle is narrow, flat, hollow-dotted, naked and ſmooth. Seeds ſmall, obovate, compreſſed a little, having little briſtles ſcattered over them, pale. Down capillary, with eighteen rays, three times as long as the ſeed, and ſcarcely toothed.

Native of moſt parts of Europe, in barren paſtures, corn fields, and by way ſides: flowering in July and auguſt.

This plant is aſtringent; and a powder or decoction of it has ſometimes been given to cattle in the bloody flux; and has been tried with ſucceſs in ſimilar complaints of the human body. Farmers in England formerly gave it their cattle to reſtore the

[c] Woodw. Mſs. [d] Lightfoot. [e] Leers.

faculty of chewing the cud, whence it acquired the Engliſh name of Cudweed[f]. It is alſo called Chafe-weed. Gerarde calls it *Herb impious*, or *wicked Cud-weed*. Petiver names it *chilling Cudweed*, and Hill, *forked Cudweed*.

Mr. Hudſon obſerves that it varies with a very ſimple erect ſtem, and axillary ſeſſile flowers.

3. Stem one or two inches high, erect, little branched. Branches radical, bifid at the top. Leaves lanceolate, blunt iſh, preſſed to the ſtem, quite entire. Flowers from the forks and at the end of the ſtalk, ſeſſile, five-cornered and pyramidal, tomentoſe as is the whole plant, aggregate; ſurrounded with leaves[g]. Calycine ſcales three or four terminated by a thread, and between them a female flower, beſides ſix males or imperfect hermaphrodites in the centre[h].

It is probably no more, ſays Krocker, than a variety of the foregoing ſpecies. It differs however from it, in having a more ſimple ſtem, with only one branch or two at the end, and more erect: it is alſo more white and tomentoſe. The flowers are only at the end and in the uppermoſt fork. The leaves are more numerous, and preſſed cloſe to the ſtem. It is annual, like the foregoing, and flowers in auguſt.

Native of the South of France, Spain, and Sileſia.

4. Root annual. Stem two to ſix inches high, erect, much branched, leafy, downy. Leaves numerous, lanceolate, ſeſſile, downy, preſſed to the ſtem, three or four lines long[i]. Heads of flowers roundiſh, ſometimes from the ſides, with from three to five (or two to four) flowers in each. Calyx pyramidal, five-cornered, ſeſſile or on very ſhort peduncles, of a whitiſh green colour, ſhining at the top. In the very centre are four complete florets; about fifteen in the diſk, and four or five in the circumference, within the ſcales of the common calyx, with piſtils only, all fertile. Anthers of the complete florets four, with two briſtles at the baſe. Border of the florets four-cleft. Seeds of all the florets in the centre ſprinkled with very ſhort glandular hairs, and crowned with a capillary down; thoſe of the florets in the circumference very ſmooth and without a down[k]. The ſmallneſs of the heads or cluſters, and the few flowers which compoſe them, readily diſtinguiſh this ſpecies from the ſecond[l].

Native of moſt parts of Europe in ſandy paſtures, eſpecially in high grounds; alſo on walls and other dry barren places. It flowers in july and auguſt.

5. Root annual, often very long. The whole plant downy, but the down ſhorter than in the ſecond and fourth ſpecies, and of a ſilvery white. Stem from half a ſpan to a ſpan in height, leafy, much branched. Leaves about an inch long, half-ſtem-claſping, awl-ſhaped[m], ſubtomentoſe, yet ſmooth and not hirſute[n]. Flowers of both ſexes ſcattered among the leaves over moſt parts of the ſtem, almoſt always ſolitary, ſometimes on very ſhort petioles, glomerate, greeniſh white, conical, narrower than in the other ſpecies. The calyx continues, and when the plant is in a ſtate of maturity expands and forms a ring, as in *Gnaphalium ſtellatum*[o].

Native of France, Switzerland, Germany, England, in gravelly and ſandy ſoils: flowering in july and auguſt. With us it is not common; but was firſt obſerved by Mr. Dale near Caſtle-Heveningham in Eſſex; and ſince by Mr. Woodward on heaths in Derbyſhire.

6. Root annual. The whole plant very woolly, inſomuch that the heads of flowers are in a manner buried. Stem erect, a foot or eighteen inches in height, branched only at top. Leaves linear-lanceolate, two lines broad, five to ſeven long, and quite entire. Flowers glomerate, uſually terminating, whitiſh. Scales of the calyx linear, awned. Seed downy, except in the hermaphrodites. The flowers are female in the circumference, androgynous in the centre, and very ſmall[p].

Native of Sweden, Germany, France, Switzerland, Carniola, in ſandy ſoils; flowering in july and auguſt.

7. Height about ſix inches; the whole plant hoary, and terminated by an elegant lanuginous ſtar formed of oblong ſpreading leaflets of unequal lengths. In the centre of this is a head of flowers which are hermaphrodite, the corolla yellow and five-cleft, the anthers acuminate; the ſtyle whitiſh, the germ ſtreaked ſmooth dilated at the end and crowned with little briſtles, which when viewed with a magnifier appear feathered, the ſtigma longer than the anthers. Round this principal head on radiating very lanuginous bracteæ ſit other ſmaller heads in number as far as ſeven, in which ſome of the flowers are female ſmall four-cleft, with a long ſtyle and a bifid ſtigma; others are incomplete, yellow, and deſtitute of genuine ſtamens, ſtyle and germ. The middle head therefore is that of a Gnaphalium, and the ſide ones are thoſe of a Filago[q]. Perennial. It flowers in june and july.

Native of the mountains of Germany, Dauphiné, Switzerland, (where Ray found it on la Dolaz, one of the high points of mount Jura) the Valais, Auſtria, Carinthia, Carniola. Introduced in 1776, by Profeſſor de Sauſſure[r].

β. This differs from the other; 1. in having a ſlender root and ſhort leaves, whereas that has a large root and oblong leaves: 2. in having flowers of a very dark brown violet colour, whereas in the other they are pale yellow.

Native of Italy, as on Monte Baldo near Verona, and in Germany. Probably in no wiſe different from the other[s].

PROPAGATION AND CULTURE.

All theſe, except the laſt, are annual plants, and being conſidered as weeds, are never cultivated except in botanic gardens. They may be propagated from ſeeds ſown in the autumn or ſpring, where they are to remain; and require no culture but to be thinned where they are too cloſe, and to be kept clean from weeds.

[FILIX, (*from filum, a thread*) or Fern.

The plants that paſs under this general denomination, conſtitute the firſt order of the claſs Cryptogamia in the ſyſtem of Linneus, called CRYPTOGAMIA FILICES. The fructification in this natural order differs eſſentially from all others, at leaſt in its ſituation: being generally diſpoſed either in ſpots or lines on the under ſurface of the fronds or leaves. There being no certain diſtinctions in the fructification ſufficient to eſtabliſh the genera, and the parts being too ſmall to be obſerved without the aſſiſtance of conſiderable magnifiers, the genera are chiefly diſtinguiſhed by the diſpoſition of the ſeeds under their covers.

The general ſtructure of the fructification in this order is the following. The *calyx* is a ſcale, ſpringing out of the leaf, opening on one ſide. Under this ſcale, commonly ſupported upon little foot-ſtalks, but ſometimes ſeſſile, are *globules* for the moſt part encompaſſed by an elaſtic ring; theſe burſt with violence, and ſcatter a powder, which is ſuppoſed to be the ſeed. Theſe globules or ſeed-veſſels are covered by a very fine, thin, ſemitranſparent ſkin, which burſts open before the ſeeds are ripe. When they are ripe, the ring or cord endeavours to become ſtraight, and by its elaſticity tears open the capſule, which then forms two hemiſpherical cups, like that of the *Anagallis*. This curious mechaniſm

[f] Lightfoot, Withering, Ray. [g] Linn. ſpec. D'Alſo, Krocker. [h] Villars. [i] Woodw. Mſs. [k] Stokes in With. [l] Ray. [m] Woodw. Mſs. [n] Linn. [o] Krocker. [p] Scopoli, Krocker, Leers, Haller. [q] Scopoli. [r] Hort. kew. [s] Ray.

may be obſerved by the aſſiſtance of a good ſingle microſcope, with a reflecting ſpeculum, during the months of ſeptember and october, in *Pteris aquilina*, or common Brakes, and *Aſplenium ſcolopendrium* or Hart's-tongue. The powder which is diſperſed in this operation is ſo minute as hardly to be viſible to the naked eye[1]. That it is the ſeed has been proved by actually raiſing plants from that of the Hart's-tongue, by Morriſon; and lately in the moſt ſatisfactory manner by Mr. John Lindſay, ſurgeon in Jamaica, from Polypodium lycopodioides[2]. Hedwig thinks that he has detected male flowers, or anthers, either ſeſſile, or elſe on a very ſhort filament, ſcattered over the back of the frond, of an ovate or ſubglobular form.

From this ſingularity of the fructification being on the back or lower ſide of the leaf, the older botaniſts named the order in which they ranged the Ferns, *Epiphyllo ſpermæ* and *Dorſiferæ*.

Since the late diſcoveries of Hedwig and others, Equiſetum, Salvinia, Marſilea, Pilularia, Iſoetes, which ſtood among the Ferns, together with Lycopodium and Porella, which were placed in the order of Muſci by Linnæus, have been united to form a new order, entitled MISCELLANEÆ, which now ſtands firſt of the claſs Cryptogamia, in Linnæus's Genera Plantarum, as publiſhed by Schreber.

The uſes of the Ferns are little known. Few of them are eſculent. They have a diſagreeable heavy ſmell. In large doſes they deſtroy worms; and ſome of them are purgative. The aſhes produced by a ſlow incineration of the green plants, contain a conſiderable portion of vegetable alkali, and are generally ſold under the name of aſh-balls, to make lye for waſhing linen[3]. Common brakes, cut down when fully grown and dried, makes very good litter; and this, with ſome others, forms a thatch more durable than ſtraw.

South America and the Weſt India iſlands furniſh abundance of ſpecies, many of which grow to a great ſize, and others are very ornamental plants in our hot-houſes.

For particulars concerning the genera and ſpecies of this order, ſee *Acroſtichum, Adiantum, Aſplenium, Blechnum, Cænopteris, Hemionitis, Lonchitis, Marattia, Meniſcium, Onoclea, Ophioglo ſſum, Oſmunda, Polypodium, Pteris* and *Trichomanes*.

DESCRIPTION, *&c.*

It is a ſmall tree or rather ſhrub, very buſhy, thorny, and growing to the height of eight or ten feet. *Stem* erect, branching, round, leprous, aſh-coloured. Branches with their ſubdivions alternate, patulous, round, thorny, dotted with tubercles, bay-coloured. Suckers at firſt without thorns, but ſoon acquiring them, ſcarcely pubeſcent, purpliſh. Thorns lateral or axillary, ſolitary, ſubulate, patulous, longer than the petiole, the upper ones gradually ſmaller. *Leaves* alternate, petioled, ſpreading, ovate or oval, ſharp, crenulate-ſerrate, almoſt entire at the baſe, ſmooth and ſhining, of a firm texture, and reſembling thoſe of the Plum; the midrib beneath very little prominent, and the veins hardly viſible; flat, bright green, ſometimes purpliſh about the edges, eighteen to twenty-four lines long, and fifteen to twenty lines broad: petioles one-ſixth of the length of the leaves, round, pubeſcent, red. Racemes terminating, erect, pedunculed. Flowers two to ſeven pedicelled. The males ochro-leucotes, four lines in breadth: in the garden only one or two in a raceme, the lateral flower moſtly abortive; females herbaceous yelloviſh, one or two lines in diameter: in the garden ſolitary. The fruit is the ſize and ſhape of a ſmall Plum, green when young, of a beautiful red when ripe, and finally of a dark violet colour: the ſkin is very thin, and the fleſh tranſparent red, of the ſame conſiſtence with our common Plums: in the middle are a dozen or fourteen ſmall kernels, the ſize of thoſe in the apple, and nearly of the ſame ſhape; they are bitteriſh, like our Apricot kernels, and covered with a tender ſhell. The natives eat the fruit; it is ſweet, but leaves a ſlight ſharpneſs in the mouth. An iſland on the coaſt of Madagaſcar is covered with theſe trees; and becauſe they reſemble the European Plum tree, the ſailors have named the iſland *Iſle aux Prunes*, or *Plum-tree Iſland*.

This tree was firſt obſerved by M. Poivre and M. Commerſon on the iſland of Madagaſcar. Both male and female trees have flowered in the Paris garden, but have been hitherto barren: they have not however yet been obſerved to flower at the ſame time[4].

M. L'Heritier has given two plates, the firſt repreſenting the plant as it appears in the green-houſe, and the ſecond the plant in its wild ſtate.

It was introduced here in 1775, by Monſ. Richard, and flowers in june and july[5].

Stem round, climbing; leaves ovate terminated by a tendril.

2. Flagellaria repens.

Lour. cochinch. 212. *Rumph. amb.* 5. 490. *t.* 184. *f.* 1.

Stem angular, creeping, leaves jointed in pairs.

DESCRIPTIONS, *&c.*

1. A shrub taller than a man. Branches distich, scaly or sheathed at the base. Leaves ending in a tendril, as in *Gloriosa*, all protected by a long entire sheath. Flowers in a panicle at the end of the stem. It seems to bear a near affinity to the Cane and Rushes [a].

Loureiro thus describes it. Stem perennial, round, twenty feet high, climbing, with few branches. Leaves simple, oblong-ovate, acuminate three-nerved, smooth, alternate, on sheathing, unarmed petioles. Flowers white, in a loose terminating raceme. Calyx six-parted. Stamens eight, short. Fruit a smooth red berry, juicy, and including one seed.

Gærtner (p. 61.) has described a fruit under the name of *Flagellaria*, which he supposes to be different from this of Linnæus's.

Native of the East Indies, Cochinchina, and of Guinea. Introduced in 1782, by the Earl of Tankerville and Dr. Pitcairn [b].

2. Stem perennial, twelve feet high, branched, unarmed, subparasitical, or creeping up trees by lateral fibres, but preserving its original root. Leaves linear, appendicled at the middle joint, smooth, alternate, half-stem-clasping. Flowers terminating, with a long bundled spadix, and a linear common spathe. Calyx none. Stamens six, dilated at the base. Stigma sessile, three-parted. Berry smooth, red, including one seed.

Native of Cochinchina.—Rumphius has two other species figured in the same plate 184 [c].

PROPAGATION AND CULTURE.

Sow the seeds in small pots of light earth, plunge them in the bark-bed; when they are fit to transplant, place them single in small pots, shading them till they have struck root, and watering them gently.

[FONTANESIA. *(So named by Billardiere in honour of Mons. Desfontaines, of the royal academy of sciences at Paris.)*

Billardiere ic. fyr. 1. 1.

Class. 2. 1. Diandria Monogynia.

Nat. order of *Sepiariæ.—Jasmineæ* Juss.

GENERIC CHARACTER.

CAL. four-parted, inferior, very small, permanent, blunt at the ends.

COR. two petalled: *petals* two-parted, parts ovate obtuse concave.

STAM. *Filaments* two, long, filiform, inserted into the claws of the corolla. *Anthers* oblong, two-grooved.

PIST. *Germ* ovate. *Style* compressed, shorter than the stamens. *Stigmas* two, inflex-hooked.

PER. *Capsule*, not opening, subovate, emarginate, compressed-membranaceous, in the centre two-celled (very rarely three-celled, three-winged.)

SEEDS solitary, oblong-columnar.

ESSENTIAL CHARACTER.

Cal. four-parted, inferior. *Petals* two, two-parted. *Caps.* membranaceous, not opening, two-celled, cells one-seeded.

SPECIES.

1. Fontanesia phillyreoides.

Billard. fyr. dec. 1. *p.* 9. *t.* 1.

Leaves ovate-oblong sharp at both ends, flowers in racemes.

DESCRIPTION, *&c.*

Stem frutescent, erect, twelve feet high. Branches opposite, erect, the younger ones quadrangular. Leaves evergreen, opposite, veined underneath; the lower ones ovate: petioles short, knee-jointed. Flowers axillary yellow.

The corolla may be considered as one-petalled and four-parted, with two of the parts more deeply cut, for the filaments are inserted into the corolla. It is allied therefore to Fraxinus and Chionanthus; but it differs from the first in having a two-celled fruit; from the second in the fruit being a capsule, not a drupe.

Native of Syria, between Laodicea and mount Cassius [a].

FONTILAPATHUM. See *Potamogeton*.

FONTINALIS, (a fonte. *Those mosses usually growing in springs.*

Lin. gen. 1190. *Schreb.* 1655. *Dill. muse.* 254. Cryptogamia Musci, or Mosses.

GENERIC CHARACTER.

Capsule oblong with the mouth ciliate; opening with an acuminate lid; covered with a sessile, smooth, conical *veil*; and included in a pitcher-shaped imbricate *perichætium*.

SPECIES.

Only four species are recited in Syst. veget. They are all natives of England, and may be found in Mr. Hudson's Flora Anglica. The three first, viz. *F. antipyretica, minor*, and *squamosa*, are water-mosses: the last, *F. pennata* grows on trees.

Dr. Withering has two more species, *F. capillacea, Dillen.* 33. 5. *Dickson*, 2. 1. and *alpina, Dickf.* 2. 4. 1.

Several new species have been discovered by Swartz in the West Indies; and one in Cochinchina by Loureiro.

[a] Linn. and Juss. [b] Hort. kew. [c] Loureiro. [a] Billardiere.

FONTINALIS. See *Bryum*, *Polygonum amphibium*, and *Potamogeton*.

FOOL'S-PARSLEY. See *Æthusa*.

FORSKOHLEA. *(So named in memory of Peter Forskähl, a Swede; born in 1732; he was Professor at Copenhagen; travelled at the expence of the King of Denmark into Egypt and Arabia; and died in the latter, of the plague, on the 11th of July, 1763.)*

Lin. gen. Reich. n. 639. *Schreb. n.* 687. *mant.* 11. *Gærtn. t.* 68. *Juss.* 403. Caidbeja. *Forsk. flor.* 82.

Class. 8. 4. Octandria tetragynia.

——10. 4. Decandria pentagynia.

Nat. order of *Urticæ* Juss.

GENERIC CHARACTER.

CAL. *Perianth* four or five-leaved, erect: *leaflets* linear-lanceolate, parallel, acute, permanent.

COR. *Petals* eight or ten, rude, spatulate, concave, erect, withering, shorter than the calyx, the claws the length of the border.

STAM. *Filaments* eight or ten, filiform, each within each petal, elastic, the length of the calyx. *Anthers* twin, roundish.

PIST. *Germs* four or five, distant, oblong, woolly. *Styles* bristle-shaped. *Stigmas* simple.

PER. none. (Capsules five, woolly, ovate, acuminate at both ends, compressed, one-celled, not opening, *G.*)

SEEDS four or five, oblong, compressed, attenuated to both ends, interwoven with wool. (Solitary, *Gærtn.* who names capsules, what are here called seeds.)

OBS. *The number varies in the parts of fructification, and is extricated with difficulty, on account of the wool in which they are involved.—The number of capsules varies from three to five. G.*

ESSENTIAL CHARACTER.

Cal. four or five-leaved, longer than the corolla. *Petals* eight or ten, spatulate. *Peric.* none. *Seeds* five, connected by wool. (*Capsules* five, woolly. *Seeds* solitary, *G.*)

SPECIES.

Lin. syst. 437. *Retz. obs.* 3. *n.* 50. *Murr. in Comm. gott.* 1784. *p.* 24. *t.* 2.

Strigose: *leaves* lanceolate, *the teeth* thorny-bristle-shaped, *calycine segments* lanceolate-subulate.

DESCRIPTION, &c.

1. Root annual. Stem two feet high, panicled, round, hispid, red; with alternate branches. Leaves alternate, petioled, ovate, marked with lines, and five or six serratures about the edge, hispid, and the hairs of the upper surface hooked. Petioles round, shorter than the leaves. Flowers axillary, in pairs, sessile, rough-hairy, deciduous with the fruit, when that is ripe[a].

According to Jacquin, the stem is a foot or a foot and a half high, partly red, partly pale green with blood-red dots, hispid with white hairs and upright. Leaves entire at the base, loosely serrate, sharp, very pale green, ciliate with short hairs, hooked at the end, whence they adhere to any thing. Petioles round and hispid. Bracles lanceolate, acuminate, hirsute. Calyx commonly five-leaved; leaflets flat, unequal, extremely hirsute. Corolla compressed, petals usually eight. The whole style extremely hirsute.

[a] Linn.

Native of Egypt. Introduced in 1770, by Monf. Richard. It flowers in july and auguſt.

2. Stem ſhrubbyiſh, ſmooth, reſembling that of the foregoing, whitiſh and woody at the baſe. Leaves oval, petioled, alternate, with three or four angles or teeth on each ſide, much ſmaller than in the foregoing ſpecies, white-tomentoſe underneath, adhering by the roughneſs on the upper ſurface, as in *F. tenaciſſima*. Flowers axillary, ſeſſile, ſmaller than in the firſt ſpecies; petals white. Segments of the calyx whitiſh, and reſembling a corolla[b].

Native of the Cape of Good Hope; Introduced in 1774. It flowers in june and july. Perennial[c].

3. Annual. Adhering like the others. Stem red. Leaves with four and ſometimes only three ſmall teeth on each ſide, ending in a ſmall ſpine; not white underneath, but adhering by little ſpikes on the nerves. Piſtils three[d].

Native of the iſland of Teneriffe. Introduced in 1779. It flowers in july and auguſt[e].

FORSTERA. *(Named in memory of John Reinhold Forſter, the father, and George Forſter, the ſon, who in a voyage round the world collected and deſcribed many new genera and ſpecies of plants.)*

Lin. ſuppl. 59. *Gen. Schreb.* 1379. *Juſſ.* 423.

Claſſ. 20. 1. Gynandria Diandria.

GENERIC CHARACTER.

CAL. *Perianth* double: *outer* inferior, three-leaved, lateral; leaflets oblong, ſharp: *inner* ſuperior, ſix-cleft; leaflets erect, oblong, concave.

COR. one-petalled, tubulous-bell-ſhaped: *tube* length of the calyx: *border* ſix-parted; *diviſions* oblong, obtuſe, patulous, reflex at the tip, equal.

Nectary two ſmall ſcales, obovate, petal-form, fixed to the ſtyle on both ſides under the ſtigma.

STAM. *Filaments* two, very ſhort, each fixed to the ſtyle between the ſtigma and a ſcale of the nectary under the ſtigma.

PIST. *Germ* inferior oval. *Style* cylindric, erect, the length of the tube of the corolla. *Stigmas* two, broad, ſpreading, ſomewhat bearded.

PER. *Capſule* oval, one-celled.

SEEDS numerous, ſhaped like ſaw-duſt, fixed to a columnar receptacle.

ESSENTIAL CHARACTER.

Perianth double: *outer* inferior, three-leaved; *inner* ſuperior, ſix-cleft. *Cor.* tubular.

SPECIES.

1. Forſtera ſedifolia.

Lin. ſyſt. 819. *ſuppl.* 407. *Forſt. aff. nov. ups.* 3. *p.* 184. *t.* 9. *Fl. auſtr. n.* 324.

DESCRIPTION, &c.

Stem herbaceous, proſtrate, aſcending, a hand in height, ſomewhat branched. Leaves imbricate, ſeſſile, obovate, ſharpiſh, quite entire, ſmooth, preſſed to the ſtem, from ſpreading reflex at the tip, without veins, ſmall. Peduncles ſolitary, one-flowered, terminating, erect, red, long. Flowers white, except at the throat and inſide of the calyx, where they are red.

According to Forſter (in Act. upſ.), the ſtem is flexuoſe, jointed, ſlender, brown. Leaves acute, fleſhy. Peduncles filiform, very long, very ſeldom two-flowered.

Native of New Zealand, on the tops of the higheſt mountains[f].

Gærtner has a plant which was given him by Forſter under the name of *Forſtera glabra*, and which he calls *Athecia glabra*. He deſcribes the calyx as five-parted and ſuperior, with linear-lanceolate permanent leaflets. The fruit an inferior berry, ovate, fleſhy, becoming finally coriaceous and wrinkled, crowned with the calycine leaflets, and within them with a flat area, having a little teat in the middle, and one-celled. Seed ſingle, large, of an oblong ſpheroidal form, marked with a depreſſed longitudinal line, reſembling a ſpurious ſuture, produced at the

[b] Linn. ſuppl. and Retz. [c] Hort. kew. [d] Retz. and Murr. [e] Hort. kew. [f] Linn. [a].

baſe into a conical crooked beak, of a reddiſh bay-colour, ſmooth and very hard. The ſituation of the embryo is ſingular and very unuſual, for it is not only excentrical, or placed without the axis, but one edge of the cotyledons or lobes faces the back, and the other the belly of the ſeed.

FORSYTHIA. See *Decumaria*.

FOTHERGILLA. (*In memory of John Fothergill, M. D. an eminent phyſician, and a patron of Botany; who cultivated a variety of the moſt curious plants in his garden near London.*)

   Mill. ic. t. 1.
   β. F. acuta. *Narrow leaved Fothergilla.*
   F. Gardeni. *Jacqu. collect.* 1. 97.

DESCRIPTION, *&c.*

A tree, having the appearance and leaves of Alder. Leaves alternate, petioled, wedge-ſhaped, entire, ſerrate at the tip, ſerratures very large and few, the upper ſurface green, the lower hoary, the younger ones white with nap underneath. Flowers in a cloſe ſpike at the end of the ſtem, like an oblong head, and white. Capſules large, ovate, very hirſute, ſharp, two-celled: the valves opening into four points, until the ſeeds are ripe. The flowers come out in the beginning of ſpring from the buds at the end of the branches before the leaves. The flower is an ament. The fruit reſembles that of *Hamamelis*, but the flower is very different*.

Native of North America: Introduced in 1765, by Mr. John Bulh. It flowers from april to june†.

β. Jacquin deſcribes this as a branching ſhrub, with ferruginous round branches. Leaves oblong, obſcurely crenate at top, on ſhort petioles, alternate, ſmooth. Spike at the end of the branchlets, ſeſſile, ovate, cloſe. Flowers ſweet-ſmelling, honied, ſeſſile. The one-leaved perianth is an ovate, obtuſe, concave, entire ſcale, with black hairy dots ſcattered over it, and ciliate with black hairs. Corolla none. Filaments about eighteen, white, filiform, thickiſh, almoſt upright, twice as long as the calyx. Anthers roundiſh, twin, yellow. Germ green, roundiſh, bifid. Styles two, awl-ſhaped, upright the length of the ſtamens. Stigmas ſimple, ſharp. Capſule two-celled. Seeds ſolitary.

Native of Carolina.

DESCRIPTIONS, *&c.*

1. This ſpecies is ſufficiently diſtinguiſhed by the long ſlender runners, which it throws out from the root, and by means of which it increaſes abundantly—by its ternate leaves—and its remarkable feſhy receptacle commonly called a berry, but having the outer ſurface ſtudded with the ſeeds. From the firſt and laſt of theſe characters it obtained the Engliſh name of *Strawberry:* for it is a plant whoſe running ſtems are ſtrewed (anciently *ſtrawed*) over the ground, and whoſe fruit is uſually regarded as a berry.

In German it is *Erdbeere*; in Daniſh *Jordbær:* (theſe convey the ſame idea with the Engliſh name,) "*humi naſcentia fraga:*" in Swediſh *Smultron*, in Smoland *Jordbar* (Earth-berry), in Dalekarlia *Jolebar*, in Gothland *Roſbar*; in French *le Fraiſier, la Fraiſe*; in Italian *Fragaria, Fragola, Fravola*; in Spaniſh *Freſera, Freſa*; in Portugueſe *Morangueiro, Fragaria, Morango*; in Ruſſian *Semljanica.*

I have recited the moſt remarkable varieties; but ſince the cultivation of this delicate and ſalutary fruit has become ſo extenſive, and different parts of the world have furniſhed ſeveral remarkable ones, varieties are daily increaſing, and certainly may be multiplied by the mixture of the farina, and ſowing the ſeeds.

It is obſerved by Mon. Duhamel, that in our European Strawberries there are *generally four* ſtamens to each petal, but in thoſe of America five or ſix: ſo that when the flowers of the latter have the regular number of petals, they have from twenty-five to thirty ſtamens; but when they have ſeven petals, the number of ſtamens is from thirty five to forty-two. In the European Strawberries when any ſupernumerary petals are placed in a row before the regular ones, each diminiſhes the number of ſtamens by one or two; but when they are placed behind the regular petals, the number of ſtamens is not diminiſhed.

α. The common Wood Strawberry of Europe has the leaflets oval-lanceolate, acutely ſerrate; the petioles woolly; the runners ſlender, ſmooth, often tinged with purple: peduncles with two or more flowers. The fruit ſmall, and uſually red; with us it has commonly little flavour, becauſe the plants are too much ſhaded in woods and hedges; the *mountainous* Strawberries of warmer and drier countries, though they uſually grow among buſhes, yet enjoying more ſun, and a drier air and ſoil, are much higher flavoured and larger than ours. The ſubordinate varieties of this are] 1. The White Wood Strawberry, which ripens a little later in the ſeaſon, and is by many perſons preferred to it for its quick flavour, but as it ſeldom produces ſo large crops of fruit as the red ſort, it is not very generally cultivated.

[The Alpine Strawberry is a larger plant than that which grows in our woods, the ſtem higher, the leaves broader, the fruit larger, red and uſually much pointed, ſometimes white. It is well flavoured, and the plants being great bearers from june till the autumn froſts put a ſtop to them, the Alpine Strawberry is very valuable. The reaſon of its long continuance in fruit is, that the runners which it throws out during the ſummer ſhoot up into flower and fruit the ſame year, more freely than the others. Mr. Miller, who makes this a variety of the Scarlet Strawberry, ſays that the Dutch gardeners entitle it *Everlaſting Strawberry.*

The rough-fruited or prickly Strawberry is nothing but a mere accidental variety. The flower is greeniſh; the fruit harſh, rough and prickly, of a greeniſh colour with ſome ſhow of redneſs. John Tradeſcant the elder firſt took notice of it in a woman's garden at Plymouth: her daughter had gathered it in the country and ſet the roots there*. Merret afterwards obſerved it in Hyde Park and Hampſtead wood.]

β. The Hautboy Strawberry has been long cultivated in the Engliſh gardens, and is very different from the reſt in leaf, flower and fruit. There is an improved variety of it, commonly called the Globe Hautboy; the fruit of which is larger, and of a globular form. Where theſe are neglected, they degenerate to the common Hautboy; but where the ſoil is good, and the culture well managed, the plants will produce a great quantity of large well-flavoured fruit.

[The Hautboy is very apt to degenerate, and to produce only dry effete fruit. This, according to Monſ. Duhamel, is owing to there being two ſorts of plants, one bearing male, the other female or rather imperfect hermaphrodite flowers; for they have thick, ſhort filaments, with very ſmall effete anthers. The former of theſe, being reputedly uſeleſs, are carefully deſtroyed, and hence not only the ſeeds become abortive, but the receptacle, which we commonly call the fruit, ſmall and juiceleſs. This may be remedied, either by planting a few of the male plants, or of the ſcarlet or pine Strawberry among the Hautboys. M. du Cheſne, who has writ a treatiſe in French on the ſubject of Strawberries, having ſowed the ſeeds of Hautboys, had about an equal number of male and female plants.—Retzius alſo informs us, that ſome of the plants produce male flowers, and are conſtantly barren, others hermaphrodite and always fertile.

[The Bohemia Strawberry of Parkinſon ſeems to be the Hautboy; but he mentions nothing of the high muſky flavour peculiar to it; and by Ray's account it ſhould ſeem to be what we now call the Alpine Strawberry; for he ſays it differs in nothing from the Wood Strawberry, but in being nearly double the ſize in all its parts, and that the fruit is not ſo pleaſant, but ſweeter. Parkinſon's relation however is very different: "that it is the goodlieſt "and greateſt, both for leaf next to the Virginian, "and for beauty far ſurpaſſing all, for ſome of the "berries have been meaſured to be near five inches "about."

I know not upon what authority Mr. Miller aſſerts that the Hautboy came originally from America.]

γ. The Chili Strawberry was brought to Europe by Monſ. Frezier, *an engineer, who was ſent* to America by the King of France: it was firſt planted in the Royal Garden at Paris, whence it was communicated to ſeveral curious perſons in Holland, and in the year 1727, Mr. Miller brought a parcel of the plants to England, which were communicated to him by Mr. George Clifford, of Amſterdam, who had large beds of this ſort growing in his curious gardens at Hartecamp. The leaves are hairy, oval, and of a much thicker ſubſtance than any ſort yet known, and ſtand upon very ſtrong hairy foot-ſtalks; the runners from the plants are very large, hairy, and extend to a great length, putting out plants at ſeveral diſtances. The peduncles are very ſtrong; the leaves of the calyx are long and hairy. The flowers are large, and are often deformed; and ſo is the fruit, which is very large, and when cultivated in very ſtrong land, the plants produce plenty of fruit, which is firm, and very well flavoured; but as it is a bad bearer in moſt places where it has been cultivated, it has generally been neglected.

* Ger. emac.

[In

[In the Chili Strawberry, says Monſ. Duhamel, the flowers which we have in Europe are imperfect hermaphrodites, the anthers being ſmall and without pollen; no ſeed therefore is produced unleſs the piſtils be impregnated by the pollen of ſome other, which has perfect flowers: and this has actually been done.

Frezier's account of the fruit is that it uſually attains the ſize of a walnut, but is ſometimes as large as an egg, that it is of a paler red than the European Strawberry, and not ſo quick in its flavour. The flowers conſiſt of more than five or ſix petals, theſe are not heart-ſhaped, but variouſly inflected and ſinuous, they are white but with a ſlight tinge of yellow at the claws; filaments ſhort and broadiſh, anthers from a broad baſe cuſped at the end, at firſt pale but afterwards brown; ſtyles yelloviſh, and a curled ſtigma when viewed through a glaſs granulous. The flowers have ſomething of the ſmell of the Hawthorn. The calyx, peduncles, flowering ſtems, and petioles are very hairy. The leaves on their upper ſurface are dark green and hairy, on their lower whitiſh and ſanguinous; the ſerratures about the edge are broad and large.]

2. The Scarlet Strawberry is the ſort which is firſt ripe, for which reaſon it merits eſteem, had it nothing elſe to recommend it; but the fruit is ſo good, as by many perſons of good taſte to be preferred to moſt others. This was brought from Virginia, where it grows naturally in the woods. It is very different from the Wood Strawberry in leaf, flower and fruit.

[The leaves are dark green and of a more even ſurface than the others; the flowering ſtems are ſhorter, and the fruit is frequently concealed among the leaves. Parkinſon obſerves, that ſcarce one fruit can be ſeen ripe among a number of plants, ſo that probably in his time the culture was not underſtood.

4. The Pine Strawberry has lately been introduced into the Engliſh gardens. Some affirm that it was brought from Louiſiana, others from Virginia; but Mr. Miller received ſome plants of it from a curious gentleman of Amſterdam, who aſſured him they were brought from Surinam. The leaves have a great reſemblance to thoſe of the Scarlet Strawberry; but are larger, of a thicker ſubſtance, and the indentures of their edges are blunter: the runners are much larger and hairy: the peduncles are ſtronger, the flowers much larger, and the fruit approaches in ſize, ſhape and colour to the Chili Strawberry. As this produces a great quantity of fruit, when the plants are kept clear from runners, and the fruit is very large, it is worthy of cultivation [b].

The Pine Strawberry, according to Monſ. Duhamel is raiſed from the ſeed of the Chili Strawberry. The flower is very large, and the fruit has ſomething of the ſmell and taſte of the Pine-apple. It varies in the form; ſome being ovoid, others oblate ſpheroid, others again irregular; they are much ſmaller than the Chili Strawberry. They are ſmooth and ſhining; the ſhaded ſide yelloviſh white, with a tincture of red, and the ſeeds red; the ſide towards the ſun pale red compoſed of a mixture of red-brown and yellow; the ſeeds red-brown. The fleſh is leſs firm than that of the Chili Strawberry, but it is juicy and has a pleaſant perfumed taſte.

5. The Carolina Strawberry greatly reſembles the foregoing, but it is much leſs in all its parts; and leſs hairy; the flower-ſtems are ſhorter; the flower-buds more lengthened out, and leſs ſwoln; the diviſions of the calyx larger, and the little ones ſeldom divided; the petals rather ſmaller and ſeldom more than five in number; the fruit ſmaller, more regular in the form, of a higher colour, and the perfume not ſo pleaſant. The Pine varies little when raiſed from ſeed, whereas this varies much in the flower, fruits, &c.[c]

The Wood Strawberry has been cultivated time immemorial. With us, we can go back at leaſt to the time of Richard III. when the Biſhop of Ely cultivated this fruit in the garden of his palace in Holborn, as related in Stow's annals. The paſſage, having been minutely copied by Shakſpeare, is well known. In the account in the Remembrancer's office of the daily expenſes of Henry VII. is the following article:—Item, to a man and woman for Strawberries 8s. 4d.

Thomas Hyll (1593) informs us, that the berries be much eaten at all men's tables in the ſummer, with wine and ſugar; and that they will grow in gardens unto the bigneſs of a mulberry [d].

The other varieties were long before they came into cultivation. Gerarde (1597) makes mention of none but the common Wood Strawberry, with its ſubordinate varieties, the white and the green, which he ſays are rare. To theſe Parkinſon (1629) adds the Virginia, which we now call the Scarlet Strawberry; and the Boheмia, of which he gives the following account—"it hath been with us but of late "days. Maſter Queſter the Poſtmaſter firſt brought "them over into our country; but I know no man "ſo induſtrious in the careful planting and bringing "them to perfection in that plentiful manner, as "Maſter Vincent Sion, on the Bank ſide, near Paris "garden ſtairs, who from ſeven roots, in one year and "a half, planted half an acre of ground with the "increaſe from them, beſides thoſe he gave away to "his friends."

After this, no addition ſeems to have been made to our ſtock, until 1727, when Mr. Miller imported the Chili Strawberry which Frezier had brought to Marſeilles about 1712. It flowered in the Eltham garden in the year 1730, but it had not then produced ripe fruit. In 1720, Bradley ſays we have only three ſorts of Strawberries, the Scarlet, the Hautboy or great White Strawberry, and the Wood Strawberry. —Mortimer has the Red Wood, White Wood, Long Red, Polonian, and Green Strawberry; he ſpeaks of the Scarlet as having been lately introduced from New England.

The berries, either eaten alone, or with ſugar, or with milk, are univerſally eſteemed a moſt delicious fruit: they are grateful, cooling, ſubacid, juicy, and have a delightful ſmell. Taken even in large quantities they ſeldom diſagree with the ſtomach. They promote perſpiration, impart a violet ſcent to the urine, and diſſolve the tartarous incruſtations upon the teeth. Perſons afflicted with the gout or ſtone have found great relief by uſing them profuſely. Linnæus informs us, that by eating plentifully of them every day, he kept himſelf almoſt free from the gout. Hoffman affirms, that he has known conſumptive people cured by them. The bark of the root is aſtringent, like the Tormentil, and the reſt of its congeners [e].

Monſ. Ducheſne publiſhed a treatiſe on the Strawberry at Paris in 1766.

2. The ſcape or flowering-ſtem of this is longer than it uſually is in the common Wood Strawberry, the petals are ſmaller, and the calyxes are gaſhed [f]. This however is frequently the caſe with the common wild ſort in woods [g]: and the others are very inconſiderable differences, eſpecially in a genus ſo liable to variation as this. Other petty diſtinctions, ſuch as that the leaves are ſmaller in winter, and their ribs leſs branched; the runners more ſlender and productive, the fruit more oblong or pyramidal [h]; will not perſuade us to ſeparate this from the foregoing as a ſpecies. Even the remarkable difference of ſimplicity in the leaves, cannot make us regard it as any thing more than a ſingular variety; for plants raiſed from the runners will ſometimes have ternate leaves, and ſeedling plants will alſo ſometimes have them. It was originally raiſed at Verſailles by M. Ducheſne in the year 1761, from ſeeds of the Wood Strawberry [i].—It agrees with its parent in the time of flowering and fruiting; nor does the form, ſize or flavour of the fruit differ more from that than might be expected from culture.

3. The name of *ſterilis* or *barren* is not given to this ſpecies, becauſe it does not produce perfect ſeed,

[b] Miller's figures. [c] Duhamel. [d] Profitable Arte of Gardening, p. 107.
[e] Wither. arr. Linn. ſuec. Lightf. [f] Linn. ſyſt. [g] Reich. [h] Curtis. [i] Ibid.

for it certainly does, but because the receptacle is not fleshy and eatable. To distinguish this from the esculent Strawberry with all it varieties, it is sufficient to observe, that though the branches be trailing, yet they never creep to throw out roots; that the leaves are ovate or obovate, bluntly serrate, silky, and silvery-white underneath, with very hairy petioles; that the flower-stems are small, weak and hairy, sustaining one or at most two flowers, smaller, and with whiter petals than the foregoing. The whole plant is smaller, weaker and more hairy; the petioles and leaflets extremely hairy; the latter on the flowering plants very small, about half an inch in length, on the young plants twice as long. Stem covered with brown scales. Peduncles from an inch to an inch and half long, terminated by one flower, and having a single leaf in the middle of it, from the axil of which springs another flower. Peduncles and calyxes tinged with red. Corolla three-eighths of an inch in diameter; petals roundish, frequently emarginate.

This species is very distinct from the other; and according to the observation of Curtis, Leers, &c. its fructification has a greater affinity with *Potentilla*, between which genus and *Fragaria* this species seems to be the link.—It flowers earlier than the other, namely in march, and is common in woods and hedges, and on some heaths; in Switzerland and in Germany as well as Britain. Also in Japan.]

PROPAGATION AND CULTURE.

Strawberries in general love a gentle hazelly loam, in which they will thrive and bear greater plenty of fruit than in a light rich soil. The ground should also be moist, for if it is very dry, all the watering which is given to the plants in warm dry seasons, will not be sufficient to procure plenty of fruit; nor should the ground be much dunged, for that will cause the plants to run into suckers, and grow luxuriant, and render them less fruitful.

The best time to remove these plants is in october, that they may get new roots before the hard frost sets in, which loosens the ground; so that if the roots of the plants are not pretty well established in the ground, the plants are frequently turned out of the ground by the first thaw; therefore the sooner they are planted when the autumnal rains begin, the less danger will there be of their miscarrying; and sometimes those which are well rooted, will produce a few fruit the first year: there are some who transplant them in the spring; but where that is done, they must be duly supplied with water in the dry weather.

The ground in which these are planted should be thoroughly cleaned from the roots of Couch, and all other bad weeds; for as the Strawberry plants are to remain three years before they are taken up, if any of the roots of those bad weeds are left in the ground, they will have time to multiply so greatly as to fill the ground, and overbear the Strawberry plants. The ground should also be well trenched and made level; then the usual method is to lay it out into beds of four feet broad, with paths two feet or two feet and a half broad between each; these paths are necessary for the convenience of gathering the fruit, and for weeding and dressing the beds, and also for watering the plants; after the beds are marked out, there should be four lines drawn in each, at a foot distance, which will leave six inches space on each side, between the outside rows and the paths; then the plants should be planted at about a foot distance from each other in the rows, in a quincunx order, being careful to close the ground to the roots of the plants when they are planted; and if there should not happen rain soon after, the plants should be well watered to settle the earth to their roots.

The distance here mentioned must be understood for the Wood Strawberries only, for as the other sorts grow much larger, their distances must be proportioned to their several growths; therefore the Scarlets and Hautboys should have but three rows of plants in each bed, which should be at fifteen inches distance, and the plants in the rows should be allowed the same space from each other, and the Chili and other large Strawberries must have but two rows of plants in each bed, which should also be two feet apart in the rows; for as these grow very strong, if they have not room to spread, they will not be very fruitful.

In chusing proper plants depends the whole success; for if they are promiscuously taken from beds without care, great part of the plants will become barren; these are generally called blind, which is when there are plenty of flowers, but no fruit produced; if these flowers are well examined, they will be found to want the female organs of generation, most of them abounding with stamina, but there are few, if any styles; so that it frequently happens among these barren plants, that some of them have a part of an imperfect fruit formed, which will sometimes ripen; this barrenness is not peculiar to Strawberries, but is general to all those plants which have creeping roots, or stalks; and the more they increase from either, the sooner they become barren, and this in some degree runs through the vegetable kingdom; for trees and shrubs which are propagated by cuttings, are generally barren of seeds in two generations, that is, when they are propagated by cuttings, which were taken from plants raised by cuttings; this I have constantly found to hold in great numbers of plants, and in fruit-trees it often happens, that those sorts which have been long propagated by grafts and buds, have no kernels. But to return to the choice of the Strawberry plants; these should never be taken from old neglected beds, where the plants have been suffered to spread or run into a multitude of suckers, nor from any plants which are not very fruitful; and those offsets which stand nearest to the old plants, should always be preferred to those which are produced from the trailing stalks at a farther distance; and the Wood Strawberry is best when the plants are taken fresh from the woods, provided they are taken from fruitful plants, because they are not so liable to ramble and spread, as those which are taken from plants, which have been long cultivated in gardens.

When the plants have taken new root, the next care is if the winter proves severe, to lay some old tanners bark over the surface of the bed between the plants to keep out the frost: this care is absolutely necessary to the Chili Strawberry, which is frequently killed in hard winters, where it is exposed without any covering; therefore where tanners bark cannot easily be procured, saw-dust, or sea-coal ashes may be used; or in want of these, if decayed leaves of trees, or the branches of Ever-green-trees with their leaves upon them, are laid over the beds, to prevent the frost from penetrating deep into the ground, it will secure the plants from injury.

The following summer the plants should be constantly kept clean from weeds, and all the runners should be pulled off as fast as they are produced; if this is constantly practised, the plants will become very strong by the following autumn; whereas when this is neglected (as is too frequently seen) and all the runners permitted to stand during the summer season, and then pulled off in the autumn, the plants will not be half so strong as those where that care has been taken; and there will not be near the same quantity of fruit upon them the following spring, nor will the fruit be near so large and fair; but where proper care is taken of the plants the first summer, there is generally a plentiful crop of fruit the second spring.

As this fruit is very common, there are but few persons who cultivate it with proper care; therefore I shall give some directions for the doing it; which, if carefully practised, will be attended with success.

The old plants of Strawberries are those which produce the fruit, for the suckers seldom produce any till they have grown a full year; therefore it appears how necessary it is to divest the old plants

of them; for wherever they are ſuffered to remain, they rob the fruitful plants of their nouriſhment in proportion to their number; for each of theſe ſuckers ſends out a quantity of roots, which interfere, and are ſo cloſely matted together, as to draw away the greateſt part of the nouriſhment from the old roots, whereby they are greatly weakened; theſe ſuckers alſo render each other very weak, and hence is the cauſe of barrenneſs; for I have known where the old plants have been conſtantly kept clear from ſuckers, they have continued very fruitful four or five years without being tranſplanted; however, it is the beſt way to have a ſucceſſion of beds, that after three years ſtanding they may be taken up; becauſe by that time they will have exhauſted the ground; and it is always obſerved, that Strawberries planted on freſh land are the moſt fruitful.

The next thing to be obſerved, is in autumn to diveſt the plants of ſtrings, or runners, and all the decayed leaves, and clear the beds from weeds; then the paths ſhould be dug up, and the weeds buried, and ſome earth laid over the ſurface of the beds between the plants; this will ſtrengthen the plants, and prepare them for the following ſpring; and if after this, there is ſome old tanners bark laid over the ſurface of the ground between the plants, it will be of great ſervice to them. In the ſpring, after the danger of hard froſt is over, the ground between the plants in the beds ſhould be forked with a narrow three pronged fork, to looſeen it, and break the clods; and in this operation, the tan which was laid over the ſurface of the ground in autumn will be buried, which will be a good dreſſing to the Strawberries, eſpecially in ſtrong land; then about the end of march, or the beginning of april, if the ſurface of the beds is covered with moſs, it will keep the ground moiſt, and prevent the drying winds from penetrating the ground, and thereby ſecure a good crop of fruit; and the moſs will preſerve the fruit clean, that when heavy rains fall after the fruit is full grown, there will be no dirt waſhed over them, which frequently happens, ſo that the fruit muſt be waſhed before it is fit for the table, which greatly diminiſhes its flavour.

The ſoil in which the Chili Strawberry is found to ſucceed beſt, is a very ſtrong brick earth, approaching near to clay; in this ſoil I have ſeen them produce a tolerable good crop, and the fruit has been extremely well flavoured; and if ſome care be taken to pull off the runners as they are produced, ſo as to leave only the old plants, I make no doubt but theſe plants may be as fruitful as the common Hautboy: this I mention from one or two experiments, which have been made by my direction, and not from theory.

There are ſome perſons who are ſo fond of Strawberries, as to be at any expenſe to obtain them early in the year, and ſhould I omit to give ſome directions for this, they would ſuppoſe the book very defective; therefore I ſhall mention the practice of ſome, who have ſucceeded beſt in the management of theſe fruits.

Where there are any hot walls erected in gardens for the producing early fruit, it is very common to ſee Strawberries planted in the borders, that the fire which is applied for ripening the fruit againſt the walls, may alſo ſerve the purpoſe of bringing forward the Strawberries; but where this is practiſed, the Strawberry plants ſhould be annually renewed, taking up the plants as ſoon as their fruit is over, and all the earth of the borders ſhould be taken out, at leaſt two feet deep, and freſh earth brought in, which will be equally good for the wall trees; but, as was before obſerved, that the old plants of Strawberries only are thoſe which produce the fruit, there ſhould be a ſufficient number of plants brought up in pots, to ſupply the border annually; and the ſame muſt be done if they are to be raiſed in a common hot-bed, or in ſtoves; therefore I ſhall begin with giving directions for raiſing and preparing plants for theſe purpoſes.

The ſorts which are the moſt proper for forcing eraly, are the Scarlet, the Alpine, and the Wood Strawberries, for the Hautboy grows too large for this purpoſe. In the choice of the plants, there ſhould be an eſpecial care taken to have them from the moſt fruitful plants, and thoſe which grow immediate to the old plants; they ſhould be taken off in autumn, and each planted in a ſeparate ſmall pot filled with loamy ſoil, and placed in a ſhady ſituation till they have taken root; after which they may be removed to an open ſituation, where they may remain till the middle or end of november, when the pots ſhould be plunged into the ground up to their rims, to prevent the froſt from penetrating through the ſide of the pots; if theſe are placed near a wall, pale, or hedge, expoſed to an eaſt aſpect, or north-eaſt, they will ſucceed better than in a warm ſituation, becauſe they will not be forced too forward; the only care they require, is to ſecure them from being turned out of the pots after froſt. The ſpring following the plants will be ſo far advanced as to have filled the pots with their roots by the end of april, when they ſhould be turned out of the pots, and their roots pared; then planted into penny pots filled with the like loamy ſoil, and plunged into the ground in a ſhady ſituation, where they ſhould remain the following ſummer; during which time they muſt be duly kept clean from weeds, and all the runners muſt be taken off as faſt as they are produced; likewiſe if there ſhould be any flowers come out, they ſhould be pinched off, and not ſuffered to bear fruit, which would weaken the plants, for there cannot be too much care taken to have the plants as ſtrong as poſſible, that they may produce plenty of fruit, without which they are not worth the trouble of forcing.

About the middle of october, or earlier, if the autumn proves cold, the pots ſhould be removed into a warmer ſituation, to prepare them for forcing; for they ſhould not be ſuddenly removed from a very cold ſituation immediately into the ſtove or hot-bed, but be gradually prepared for it; but where they are deſigned for the borders near a hot wall, they may then be turned out of the pots, and planted into the borders, that they may have time to get freſh rooting, before the fires are made to heat the walls; when theſe are planted, they may be placed very cloſe to each other; for as they are deſigned to remain there no longer than till they have ripened their fruit, they will not require much room, as their roots will find ſufficient nouriſhment below, and alſo from the earth which is filled into the ſpaces between the balls of earth, about their roots; and it is of conſequence to get as much fruit as poſſible in a ſmall ſpace, where there is an expenſe to force them early. If the fires are lighted about Chriſtmas, the Strawberries in theſe borders will be ripe the end of march; or if the ſeaſon ſhould prove very cold, it may be the middle of april before they will be fit for the table.

In the management of the plants there muſt be care taken to ſupply them with water when they begin to ſhew their flowers, otherwiſe they will fall off without producing any fruit; and, in mild weather, there ſhould be freſh air admitted to them every day; but as fruit-trees againſt the wall muſt be ſo treated, the ſame management will agree with the Strawberries.

If the Strawberries are intended to be forced in a ſtove, where there are Pine-apples, and no room to plunge them in the tan-bed, then the plants ſhould be tranſplanted into larger pots in ſeptember, that they may be well rooted before they are removed into the ſtove, which ſhould not be till december; but if they are placed under a frame the beginning of november, where they may be ſcreened from the froſt, it will prepare the plants better for forcing; and thoſe who are deſirous to have them very early, make a hot-bed under frames, upon which they place their plants the latter end of october, which will bring them forward to flower, and then they remove the plants into the ſtove; when theſe plants are removed into the ſtove, they ſhould be placed as

near

near to the glaſſes as poſſible, that they may enjoy the full ſun and air; for when they are placed backward, the plants will draw up weak, and the flowers will drop without producing fruit. As the earth in the pots will dry pretty faſt when they ſtand upon the pavement of the hot-houſe, or on ſhelves, the plants muſt be duly watered; but it muſt be done with diſcretion, and not too much given, which will be equally hurtful to them; if theſe plants are properly managed, they will produce ripe fruit in february, which is as early as moſt people will chuſe to eat them.

When the fruit is all gathered from the plants, they ſhould be turned out of the ſtove; nor ſhould thoſe plants which are in the borders near the hot walls be left there after their fruit is gathered, but immediately taken up, that they may rob the fruit-trees of their nouriſhment as little as poſſible.

Where there is no conveniency of ſtoves, or hot-walls for this purpoſe, the fruit may be ripened upon common hot-beds; and though they may not be quite ſo early as with the other advantages, yet I have ſeen great crops of the fruit ripe in april, which were upon common hot-beds under frames, and executed at a ſmall expenſe in the following manner.

The plants were prepared in pots after the manner before directed, and were placed in a warm ſituation the beginning of octoher; about Chriſtmas the hot-bed was made in the ſame manner as for Cucumbers, but not ſo ſtrong; and as ſoon as the firſt violent ſteam of the dung was over, ſome old rotten dung laid over the hot-bed to keep down the heat, or where it can be eaſily procured, neats dung is preferable for this purpoſe; then the plants ſhould be turned out of the pots, and placed upon the bed as cloſe together as poſſible, filling up the interſtices between the plants with earth, afterwards the plants muſt have air admitted to them every day; and if the heat of the bed is too great, the plants ſhould be raiſed up, to prevent their roots being ſcorched; and if the bed is too cold, the ſides of it ſhould be lined with ſome hot dung: this firſt bed will bring the plants to flower by the end of february, or the beginning of march, by which time the heat of the bed will be ſpent, therefore another hot-bed ſhould be prepared to receive the plants, which need not be ſo ſtrong as the firſt; but upon the hot dung ſhould be laid ſome neats dung about two inches thick, which ſhould be equally ſpread and ſmoothed; this will prevent the heat of the bed from injuring the roots of the plants, upon this ſhould be laid two inches of a loamy ſoil; when this has laid two days to warm, the plants ſhould be taken out of the firſt hot-bed, and turned carefully out of the pots, preſerving all the earth to their roots, and placed cloſe together upon this new hot-bed, filling up the vacuities between the balls with loamy earth: the roots of the plants will ſoon ſtrike out into this freſh earth which will ſtrengthen their flowers, and cauſe their fruit to ſet in plenty; and if proper care is taken to admit freſh air to the plants, and ſupply them properly with water, they will have plenty of ripe fruit in april, which will be full two months before their natural ſeaſon.

The Alpine Strawberry will ſupply the table the whole ſummer, eſpecially if care be taken in dry ſeaſons to water the plants, without which the bloſſoms are apt to fall off, without producing fruit.

[Thus may a ſucceſſion of this delicious and ſalubrious fruit be obtained from march or april, and even earlier, by means of a hot-houſe, forcing-frame, hot-walls or hot-beds, and in the open air from june to octoher and november, ſhould the weather prove mild; for not only the Alpine but the White Wood Strawberry will continue bearing in tolerable abundance until the autumn froſts come on with ſome degree of ſeverity, eſpecially if the ſituation be warm, and the ſoil in which they grow not too light.]

There are ſome perſons ſo curious as to raiſe the plants from ſeeds, by which they have greatly improved ſome of the ſorts; and if this was more practiſed, I am certain it would be found of ſingular ſervice, where the faireſt of the fruit of each kind are choſen. The ſeeds ſhould be immediately ſown when the fruit is eaten; the beſt way is to ſow the ſeed in pots, placing them in the ſhade.

In the ſpring of the year 1724, there was ſcarcely any rain from february till about the middle of july, ſo that moſt of the Strawberries were burnt up; but a copious rain falling in july they recovered and put out abundance of flowers, which were ſucceeded by fruit that ripened in ſeptember, when the London makets were ſupplied with a great plenty.

DESCRIPTIONS, *&c.*

1. Root perennial. Stem and leaves thinly ſprinkled with white globular particles. Stems numerous, round, branched, trailing. Leaves in little cluſters, ſmall, fleſhy, rolled back ſo as to appear almoſt cylindrical, with a groove underneath, flatted at the baſe, where they are dilated into a pair of minute, membranaceous ciliate ſtipules. Flowers at the ramifications of the ſtem, and in the middle of a bundle of leaves, ſolitary, ſeſſile: calyx with five, ſix or ſeven ribs, and as many teeth, but rarely more than five: corolla purple, petals wedge-ſhaped, a little ſcolloped at the end. Nectary a yellow ſcale. Filaments flat on one ſide, convex on the other. Style deeply trifid. The flowers are elegant in form and colour, like thoſe of a little red Pink or Campion. The ſtamens and piſtil much reſemble the *Lychnis*, to which this plant is nearly allied, though ſo different in habit[a].

In ſalt marſhes, near Leghorn. In England, Mr. Goodyer found it ſept. 3, 1621, at Burſeldon ferry, Hampſhire; on the coaſts of Eſſex, Suſſex and Kent, abundantly: as in the iſlands of Sheppy and Thanet, Lovingland, juſt over the water at Yarmouth, about Thurrington in Eſſex, between Maldon and Goldhanger; in Selſey iſland, Suſſex; near Portſmouth; Tid Goat near Wiſbech; near Lynn in Norfolk.—It flowers in july and auguſt.

2. Stems procumbent, preſſed as it were cloſe to the ground, panicled and dichotomous. Leaves like thoſe of Thyme, ciliate eſpecially at the baſe[b]. Flowers violet-coloured. Native of the South of France, Apulia, Crete, Siberia, and the Cape of Good Hope.

3. Stems lying flat, ſlender, branching, with the knots about a finger's breadth from each other. Leaves four at a joint, with very ſhort hairs underneath, the edges not rolled in; petioles ſhort. Flowers in the axils of the leaves, ſeſſile: calyx tough, rigid, with five angles; teeth upright. Annual[c].

Native of the South of France, Italy and Spain. Found on the coaſt of Suſſex, by Mr. Brewer: between Bognor and Brighthelmſtone, by Mr. Hudſon. It flowers in july.

Gerarde and Ray name it *Valentia Knot-graſs.*

Theſe plants were named *Franca* by Micheli, from Giov. Sebaſt. Franchi, of Lucca, phyſician at Florence to the Grand Duke Coſmo III. Linneus changed the name to Frankenia, in order to perpetuate the name of a perſon, not of much greater celebrity.

DESCRIPTIONS, *&c.*

[Trees. Leaves oppoſite, unequally pinnate, ſeldom ſimple. Flowers in panicles at the ends of the branches. *F. Ornus* with four petalled hermaphrodite flowers. *F. excelſior*, or common Aſh, with apetalous polygamous flowers, the hermaphrodites on one tree, and the females on another[a].]

1. The leaves have generally five pairs of leaflets, (four to ſix) and one odd one, of a dark green. The flowers are produced in looſe ſpikes from the ſide of the branches, and are ſucceeded by flat ſeeds which ripen in autumn.

[The lateral buds produce the flowers, and the terminating one the leaves[b].]

Bractes linear, one on the outſide at the baſe of each pedicel. Filaments broad and flat, not ſo

[a] Withering. Relhan. Engl. Bot. [b] Stokes in Withering.

[a] Juſſieu. [b] Linn. ſpec.

long as the anthers, which are of a blackiſh purple colour[a]. There are not only hermaphrodite and female flowers, but alſo male ones, ſo that this ſpecies ſhould ſeem referable to the order triœcia[a]. Care ſhould be taken in obſerving the flowers; for in thoſe which are hermaphrodite, the germ which lies between the two ſtamens, does not grow up till ſome days after they appear, ſo that at firſt they appear to be male flowers. What Linneus calls a ſeed, others call a capſule; the ſeed being covered with a leathery kind of cruſt, which does not ſplit or open.

Varieties.

The varieties of the common Aſh-tree are, 1. That with ſimple leaves, which, however, ſometimes has them lobed and even ternate. 2. With pendulous branches, called the *Weeping Aſh*. I have for near forty years known a very fine tree growing naturally ſo, at Gamlingay in Cambridgeſhire; and it is not uncommon in trees of conſiderable age, eſpecially when growing by the water ſide, to ſee the branches hang down. This variety is now become common in the nurſeries, but they are engrafted, and carry too much the appearance of art. Imitations ſeldom are ſucceſsful, and none of the weeping trees will ever vie with the Babylonian Willow.

3. With variegated leaves, both yellow and white; or gold-ſtriped and ſilver-ſtriped, as the nurſery-men call them.

Micheli has ſome other varieties, from the different ſhape of the fruit, the ſize and form of the leaves, &c. *Nov. gen.* 227.

Name, Uſe, &c.

The Aſh in German and Dutch is *Eſche* or *Aſche*; in Daniſh and Swediſh *Aſk*; in French *le Frêne*; in Italian *Fraſſino*; in Spaniſh *Freſno*; in Portugueze *Freixo*; in Ruſſian *Jaſ*, *Jaſen*, *Jaſſen*, which name prevails in the dialects of the Sclavonian.

The Engliſh is from the Saxon *Æſc*. Ray ſays it has its name from the colour of the bark.

We muſt be careful not to confound, as ſome have done, this tree with the Mountain Aſh, which is totally different from it. This has the epithet *exceliſor* from the loftineſs of the trunk—that of *mountain*, from the loftineſs of the ſituation which it delights in.

Its uſual time of flowering is in march and april, ſometimes ſo late as may: of leafing from april 22 to may 15. Both are ſometimes much injured by ſpring froſts.

The timber of the Aſh is next in value to the oak, and in ſome places equal to it.] It is hard and tough, and of excellent uſe to the coach-maker, wheel-wright and cart-wright, for ploughs, axle-trees, fellies, harrows, and many other implements of huſbandry; for ladders, oars, blocks for pullies, &c. &c. It makes a very ſweet fuel, with little ſmoke, but is apt to crack and fly in burning.—[Anciently it was in great requeſt for ſpears.

For drying herrings no wood is like it, and the bark is good for the tanning of nets: being not apt to ſplit and ſcale, it is excellent for tenons and mortiſes; alſo for the cooper, turner and thatcher: nothing is like it for palliſade hedges, hop-yards, poles and ſpars; handles and ſtocks for tools, ſpade trees, &c. When curiouſly veined, the cabinet-makers uſe it, and call it Green Ebony[a].

By a remark in Harriſon's deſcription of England, prefixed to Holingſhed, chap. 19. edit. 1586, it is plain, that the Aſh was then eſteemed the propereſt tree for hop-poles.—" Poles are accounted to be " their greateſt charge (of hops). But ſith men " have learned of late to ſow aſhen keis in aſh yards " by themſelves, that inconvenience in ſhort time " will be redreſſed[b]."

Aſh-pollards are of great ſervice where fuel is ſcarce; a few of them will produce many loads of lop. The loppings make the ſweeteſt of all fires, and will burn well either green or dry; only if the branches are ſuffered to grow too large, the lopping will proportionably injure the tree[c].]

If a wood of theſe trees be rightly managed, it will turn greatly to the advantage of its owner; for by the underwood, which will be fit to cut every ſeven or eight years for hoops, or every fourteen years for hop-poles, &c., there will be a continual income more than ſufficient to pay the rent of the ground, and all other charges, and ſtill there will be a ſtock preſerved for timber, which in a few years will be worth forty or fifty ſhillings the tree.

The beſt ſeaſon for felling the aſh is from november to february; for if it be done either too early in autumn, or too late in the ſpring, the timber will be ſubject to be infeſted with worms, and other inſects; but for lopping pollards, the ſpring is preferable for all ſoft woods. [Mr. Boutcher recommends february.

The aſhes of the wood afford very good pot-aſh. The bark is uſed for tanning calf-ſkin: a ſlight infuſion of it appears of a pale yelloviſh colour when viewed againſt the light, but when looked down upon or placed between the eye and an opake object, it is blue. This blueneſs is deſtroyed by the addition of an acid, and alkalies recover it again. It will give a good, though not beautiful green to cloths which have been blued[d].

In the north of Lancaſhire they lop the Aſh to feed the cattle in autumn, when the graſs is upon the decline; the cattle peeling off the bark[e].—In Queen Eliſabeth's time the inhabitants of Colſon and Hawkſhead ſells remonſtrated againſt the number of forges in the country, becauſe they conſumed all the loppings and croppings, which were the ſole winter food for their cattle[f]. In foreſts, the keepers browze the deer on ſummer evenings with the ſpray of aſh, that they may not ſtray too far from their walk[g]. The leaves have been gathered to mix with tea; and poor people in ſome places have made a conſiderable advantage by collecting them for this purpoſe[h].—An infuſion of them, from half an ounce to an ounce and an half, is a very good purge; and a decoction of two drams of the bark, or ſix drams of the leaves, has been uſed to cure agues[i].]

If any cows eat of the leaves or ſhoots, the butter which is made of their milk will be rank; which is always the caſe with the butter which is made about Guildford and Godalmin, and in ſome other parts of Surry, where there are Aſh-trees growing about all their paſtures: and in good dairy countries they never ſuffer an Aſh-tree to grow.

[The truth of this fact is doubted by others; for it is certain that there is no taſte in aſh leaves to countenance the aſſertion, and that this is the next tree after the elm which the Romans recommended for fodder[k]. I have alſo paſſed much time in a country where the aſh was almoſt the only tree in the hedge-rows; and yet I never obſerved this rankneſs in the butter.

Cream is apt to turn bitter at the fall of the leaf, and the reaſon is generally thought to be, that the cattle then pick up the decayed leaves, particularly of the Aſh: but the caſe is the ſame in the great low paſtures which are open and without trees, as in upland incloſures, which abound in them. The only way to avoid the ill taſte in butter at that ſeaſon, is to churn oftener, and to ſpend the butter whilſt it is new.

The aſh is, however, a very improper tree for hedge-rows and the borders of arable land: the drip of it is very unfavourable to all other vegetable productions; it exhauſts the ſoil very much; and the roots ſpread widely near the ſurface: ſo that it injures the hedges, and impoveriſhes the crops that are ſown near them.

Nor, though it be a handſome tree, ought it by

[a] Withering. [b] Stokes in With. [c] Evelyn.

[e] Hunter's Evelyn. [f] Stokes in Withering. [g] Gilpin's for. ſcen. 2. 280. [h] Withering. [i] Withering and Stokes. [k] Pennant's tour 1772. p. 29. [l] Gentl. mag. as above. [m] Gentl. mag. as above.

any means to be planted for protection or ornament, becauſe the leaves come out late, and fall early. The fertile trees alſo generally exhauſt themſelves ſo much in bearing keys or fruit, that their foliage is ſcanty, and their appearance unſightly. The trees, however, which bear female flowers only, have a full and verdant foliage, and make a handſome figure, though late in the ſeaſon [1]. It is well calculated for ſtandards and clumps in large parks and plantations, and for groves and woods [2]. "Fraxinus in ſylvis pulcherrima."—It will grow in very barren ſoil, and in the bleakeſt and moſt expoſed ſituations [3]. It is ſo hardy as to endure the ſea winds well, and may therefore be planted on the coaſt, where few trees will proſper [4].—If planted by ditch ſides, or in low boggy meadows, the roots act as underdrains, and render the ground about them firm and hard; the timber, however, is in this caſe but of little value [5]. It was natural that our remote anceſtors, when the iſland was over-run with wood, ſhould value trees rather for their fruit than their timber: it is no wonder, then, that by the laws of Howel Dda, the price of an oak or a beech ſhould be 120 pence, while the aſh, becauſe it furniſhed no food for ſwine, was valued only at four-pence.

The Edda of Woden, however, holds the Aſh in the higheſt veneration; and man is deſcribed as being formed from it. Heſiod in like manner deduces his brazen race of men from the Aſh; and in his Theogony his Nymphs of the name Μελιαι.

It is probably owing to the remains of Gothic veneration for this tree, that the country people, in the ſouth-eaſt part of the kingdom, ſplit young aſhes, and paſs their diſtempered children through the chaſm in hopes of a cure. They have alſo a ſuperſtitious cuſtom of boring a hole in an aſh, and faſtening in a ſhrew-mouſe: a few ſtrokes with a branch of this tree is then accounted a ſovereign remedy againſt cramps and lameneſs in cattle, which are ignorantly ſuppoſed to proceed from this harmleſs animal [6]. In many parts of the highlands of Scotland, at the birth of a child, the nurſe or midwife puts one end of a green ſtick of this tree into the fire, and while it is burning, receives into a ſpoon the ſap or juice which oozes out at the other end, and adminiſters this as the firſt ſpoonful of liquor to the new-born babe [7].

It is not common to ſee the Aſh of a very great ſize: inſtances, however, of large trees are not wanting.—Dr. Plot mentions one of eight feet diameter, valued at thirty pounds.—Mr. Marſham informs us of another in Beniel church-yard near Dunbarton in Scotland, meaſuring in 1768, ſixteen feet nine inches in girt, at five feet from the ground. —Mr. Evelyn ſays that divers were lately ſold in Eſſex, in length one hundred and thirty-two feet.—Mr. Arthur Young, in his Iriſh tour, mentions ſome of ſeventy and eighty feet in height, which were only of thirty-five years growth. The trunk of one on the bank of the Avonmore was above fourteen feet round, and carried nearly the ſame dimenſions for eighteen feet. An Aſh at Dunganſtown is twelve feet round, and quite clear of branches for thirty feet, where it meaſures ten feet round, and the arms extend in beautiful forms twenty-eight yards. At Tiny-Park is another, the circumference of which in the ſmalleſt part ſomewhat exceeds nineteen feet, or ſix feet four inches diameter. At Luttrellſtown, the ſeat of the Earl of Carhampton, are ſeveral Aſh-trees from eleven to thirteen feet ſix inches round; one here was ſold for 15*l.* At Leixlip caſtle is a row of eighteen Aſh-trees, on a very bleak expoſure, meaſuring from nine to twelve feet round, with fair ſtems of conſiderable height, and fine branching heads. At Donirey near Clare caſtle in the county of Galway is an old Aſh that at four feet from the ground meaſures forty-two feet in circumference, at ſix feet high thirty-three feet; the trunk has long been quite hollow, a little ſchool having been kept in it; there are few branches remaining, but theſe are freſh, and very vigorous. Near Kenniy church in the King's county is an Aſh whoſe trunk is twenty-one feet ten inches round, and it is ſeventeen feet high before the branches break out; theſe are of enormous bulk. When a funeral of the lower claſs paſſes by, they lay the corpſe down for a few minutes, ſay a prayer, and then throw a ſtone to increaſe the heap, which has been accumulating round the root.—Finally, in the church-yard of Lochabar in Scotland, Dr. Walker meaſured the trunk of a dead Aſh, which at five feet from the ſurface of the ground, was fifty-eight feet in circumference.

It is pleaſant to obſerve that amidſt the deplorable deſtruction of valuable timber, the planting of this ſo extenſively uſeful tree has lately not been neglected; as will appear from the following account.

20 acres, by Wm. Wollaſton, Eſq. at Great Finborough, Suffolk.
35 acres, by Thos. White, Eſq. at Butsfield, Lanchester, Durham.
16 acres; and 150, 800 on 32 a. 1 rood. } by Mr. David Day, Frindſbury, Kent.
63,000, on 7 a. 9 perches. } by Edward Loveden Loveden, Eſq. Buſcot, near Fatringdon, Berks.
6000, by John Sneyd, Eſq. Belmont, Staffordſhire, between 1784 and 1786.
20,000 on 11 acres. } by Dr. Rd. Watſon, Biſhop of Llandaff, near Ambleſide in Weſtmoreland. 1788.
42,000, by George Roſs, Eſq. Cromarty.
67,500, by the Earl of Fife, in the county of Murray [8].

The facility with which the Aſh is propagated, and adapts itſelf to any ſoil or ſituation, even the worſt; the quickneſs of its growth, and the general demand for the timber in every part of the country, for a variety of rural and oeconomical purpoſes, recommend this tree very much to the planter. As a farther encouragement, Mr. Boutcher has given an inſtance of the great profit of an Aſh plantation, in a ſmall experiment, which he thus relates.

On half a rood of heavy meadow, chiefly barren red clay and moſs, he planted Aſh-trees ſix years old, and eight feet high, in rows four feet aſunder, and two feet diſtance in the row; after four years he cut them down within five or ſix inches of the ground. Having more than he wanted, in ſeven years he ſold half for pollards and hoops for 40*s.* In ſix years he cut them again, and ſold them for 50*s.* In ſix years after this he cut them again, and ſold them at the ſame price. There remained now twenty trees, intended to ſtand for timber, but he was obliged to ſell them at twenty-three years growth for 7*s.* a tree. Thus would an acre of indifferent ground properly ſituated for ſale yield in twenty-three years 115*l.* 10*s.* without any other expenſe than digging the ground for the firſt five or ſix years, and cutting the coppice. Care ſhould be taken to cut them ſlanting, with a ſharp inſtrument, leaving all the wounds ſmooth and clean. Obſerve that no price is mentioned for the firſt cutting, which he uſed himſelf; and that he found he ſhould have had at leaſt one third more for the price of the laſt cutting. He alſo found that he had planted too thick, and that he ſhould have had more wood, if the rows had been ſix feet aſunder, and the ſets three feet diſtant in the row.

2. The ſhoots of the Manna Aſh are much ſhorter, and the joints cloſer together than thoſe of the common Aſh: the leaflets are ſhorter, with deeper ſerratures on their edges, and of a lighter green: the flowers come out from the ſide of the branches, are of a purple colour, and appear in the ſpring before the leaves come out. This tree is of humble growth, ſeldom riſing to more than fifteen or ſixteen feet in height in England.

It was cultivated here in 1697, by the Ducheſs of Beaufort [9].

[1] Gentl. mag. for 1785.

[7] Tranſact. ſoc. arts. &c.
[8] Hort. kew.

The lower parts of the mountains in Calabria abound with the Manna Aſh, which grows ſpontaneouſly, and without any culture; except that the woodmen cut down all the ſtrong ſtems that grow above the thickneſs of a man's leg. Towards the end of july, the gatherers of manna make an horizontal gaſh, inclining upwards, in the bole of the tree. As the liquor never oozes out the firſt day, another cut is given on the ſecond, and then the woodman fixes the ſtalk of a maple leaf in the upper wound, and the end of the leaf in the lower one, ſo as to form a cup to receive the gum as it diſtils from each gaſh. The ſeaſon continues about a month. The men have only three carlines (*1s. 1½d.*) for every rotolo; which quantity, containing thirty-three ounces and a third, is ſold for twenty-four carlini and three quarters, or ſomewhat more than ten ſhillings; if it be in tubular pieces, the price riſes one third [a]. Theſe pieces are called *Manna in canuoli*, and theſe regular tubes are produced, by applying to the inciſion thin ſtraw, or ſmall bits of ſhrubs, upon which the manna runs as it oozes out [b].

The trees ſucceed beſt in an eaſtern expoſure, in order to warm the juices in the morning, and to inſpiſſate thoſe which the heat has ſweated out in the evening [c].

3. The petioles of this are equal; the leaflets lanceolate and equal. In the common Aſh the petioles are margined; the leaflets ovate, and the odd one larger than the reſt.—Scopoli obſerved hermaphrodite flowers on one tree, and female on another.

Mr. Miller makes two ſpecies out of one; his *F. paniculata* has only or chiefly male flowers. He thus deſcribes them.]—*F. Ornus* is a low tree, about the ſame height as the preceding; the leaves are much ſmaller and narrower than thoſe of our Common Aſh, but are ſerrate, and of the ſame dark colour. The flowers have petals. *F. paniculata* was raiſed (before 1730) by Dr. Uvedale at Enfield, from ſeeds which were brought from Italy by Dr. William Sherard.—The leaves have but three or four pairs of leaflets, which are ſhort, broad, ſmooth, of a lucid green, and irregularly ſerrate; the midrib is jointed, and ſwells where the leaflets come out. The flowers grow in looſe panicles at the ends of the branches, are of a white herbaceous colour, moſtly males, and appear in may.

4. [The fruits or keys are the ſame as in the common Aſh, but much ſmaller, and narrower [d].

Mr. Miller has two ſorts of this, which he thus deſcribes].—*F. Novæ Angliæ* was raiſed from ſeeds ſent from New England in the year 1724 by Mr. Moore. The leaves have but three, or at moſt four pairs of leaflets, which are placed far diſtant from each other, and the odd leaflet runs out into a very long point, they are of light green, and have no ſerratures on their edges. This tree ſhoots into ſtrong irregular branches, but does not grow to a large ſize in the trunk. *F. caroliniana* was raiſed from ſeeds ſent from Carolina in the year 1724 by Mr. Catesby. The leaves have ſeldom more than three pairs of leaflets, the lower being the leaſt, and the upper the largeſt; theſe are about five inches long and two broad, of a light green colour, and ſlightly ſerrate; the midrib is taper, and has ſhort downy hairs on it; the ſeeds are broader than thoſe of the common Aſh, and are of a very light colour.

[The firſt of theſe is alſo called the *White Aſh*, and the ſecond the *Red Aſh*. A third named the *Black Aſh*, and other varieties, may be found in the nurſeries.]

PROPAGATION AND CULTURE.

1. The common Aſh propagates itſelf in plenty by the ſeeds which ſcatter in the autumn, ſo that where the ſeeds happen to fall in places where cattle do not come, there will be plenty of the plants come up in the ſpring; but where any perſon is deſirous to raiſe a quantity of the trees, the ſeeds ſhould be ſown as ſoon as they are ripe, and then the plants will come up the following ſpring; but if the ſeeds are kept out of the ground till the ſpring, the plants will not come up till the year after; it is the ſame with all the ſorts of Aſh; ſo that when any of their ſeeds are brought from abroad, as they ſeldom arrive here before the ſpring, the plants muſt not be expected to appear till the next year: therefore the ground ſhould be kept clean all the ſummer where they are ſown, and not diſturbed, leſt the ſeeds ſhould be turned out of the ground, or buried too deep to grow; for many perſons are too impatient to wait a year for the growth of ſeeds, ſo that if they do not come up the firſt year, they dig up the ground, and thereby deſtroy the ſeeds.

When the plants come up, they muſt be kept clean from weeds during the ſummer; and if they make good progreſs in the ſeed-bed, they will be fit to tranſplant by the autumn: therefore there ſhould be ſome ground prepared to receive them, and as ſoon as their leaves begin to fall, they may be tranſplanted. In taking them up, there ſhould be care taken not to break or tear off their roots; to prevent which, they ſhould be taken up with a ſpade, and not drawn up as is frequently practiſed; for as many of the plants which riſe from ſeeds will out-ſtrip the others in their growth, ſo it is frequently practiſed to draw up the largeſt plants, and leave the ſmaller to grow a year longer before they are tranſplanted; and to avoid hurting thoſe which are left, the others are drawn out by hand, and thereby many of their roots are torn off or broken; therefore it is much the better way to take all up, little or big together, and tranſplant them out, placing the larger ones together in rows, and the ſmaller by themſelves. The rows ſhould be three feet aſunder, and the plants a foot and a half diſtance in the rows; in this nurſery they may remain two years, by which time they will be ſtrong enough to plant where they are to remain; for the younger they are planted out, the larger they will grow; ſo that where they are deſigned to grow large, they ſhould be planted very young; and the ground where the plants are raiſed, ſhould not be better than that where they are deſigned to grow; for when the plants are raiſed in good land, and afterwards tranſplanted into worſe, they very rarely thrive; ſo that it is much the beſt method to make the nurſery upon a part of the ſame land, where the trees are deſigned to be planted, and then a ſufficient number of trees may be left ſtanding upon the ground, and theſe will out-ſtrip thoſe which are removed, and will grow to a larger ſize.

Where people live in the neighbourhood of Aſh-trees, they may ſupply themſelves with plenty of ſelf-ſown plants, provided cattle are not ſuffered to graze on the land, for they will eat off the young plants, and not ſuffer them to grow; but where the ſeeds fall in hedges, or where they are protected by buſhes, the plants will come up and thrive.

[To theſe ſhort and imperfect directions of Mr. Miller, it may not be amiſs to add the following paragraphs from Mr. Evelyn, Dr. Hunter, and Mr. Boutcher.

If you would have a conſiderable wood of Aſh at once, prepare your ground as you would for corn, and ſow good ſtore of keys, ſome crab-kernels, &c. with oats. Take off your crop of corn in its ſeaſon, and the year following the ground will be covered with young aſhes, which will either be fit to ſtand, which I prefer, or be tranſplanted for divers years after. And theſe you will find to be far better than any you can gather out of the woods, eſpecially ſuckers which are worth nothing. The ſooner they are removed, the better; and aſhes of two years thus taken out of the nurſery, ſhall often out-ſtrip thoſe taken out of the hedge. You may keep the keys in ſand for a winter before you ſow them, in a covered airy place.

Gather the ſeeds or keys from healthy young thriving trees in october or november, having prepared

[a] Swinburn. [b] Philoſ. tranſ. vol. 60. [c] Symonds in Young's ann. 3. 161. [d] Linn. ſpec.

pared the beds, lower them about an inch, by raking ſome of the earth into the alleys; ſow the ſeed moderately thick, and then throw the earth back again lightly with a ſpade, or ſift it over them an inch thick, and rake it level. In ſpring with a very ſmall light iron rake, the teeth about an inch aſunder, rake off the moſs, pull up the weeds, and ſift a little earth over them again.

The ſecond ſpring, in the firſt open weather in february, rake off the earth as before very gently, ſift freſh over them half an inch thick, and in march and april the young plants will appear in plenty. In october ſift ſome coal-aſhes half an inch thick over them.

Next ſpring prepare ſome beds ſix feet wide, with a path of two between each: plant all of a ſize in each bed, at one foot ſquare, firſt ſhortening the tap-roots, and alſo the ſide ones[1].

They muſt then be planted out into your nurſery in rows three feet aſunder, and each plant at one foot diſtance, where they are to remain till they are finally planted out[1].

Mr. Boutcher recommends the ſeeds being ſpread in an airy loft, and turned till dry, which will be in three or four weeks, and then mixed with ſand; to be ſown the beginning of april on freſh mellow ſoil, on beds three and a half feet broad, with alleys eighteen inches, and covered three quarters of an inch deep. The ſeeds will not appear till the ſucceeding ſpring; during this time the beds muſt be kept clean, and in february they muſt be raked over: if a little rich mould is thrown over them, it will much promote the growth of the ſeedlings. The following february or march remove them, and plant them in drills eighteen or twenty inches aſunder, and eight or nine inches in the drill. In october remove them again, planting them in lines three and a half feet aſunder, and fifteen or ſixteen inches in the line, where they may remain three years. The trees will now be ſeven or eight feet high, of a proper ſize for extenſive plantations. Where large ones are wanted, remove them every fourth year.

Stocks for budding ſhould be planted out in the nurſery, a foot aſunder, and two feet diſtant in the rows. When they are one year old, and about the thickneſs of a bean ſtraw, they will be of a proper ſize for working. A little after midſummer is the time for the operation, and care muſt be obſerved not to bind the eye too tight. They need not be unlooſed before the end of ſeptember. In march the head of the ſtock ſhould be taken off a little above the eye, and by the end of the ſummer following, if the land be good, they will have made ſtrong ſhoots. The variegated ſorts can be increaſed only in this manner[2].

2. &c. The other ſorts are commonly propagated in the nurſeries by budding or ingrafting upon the common Aſh; but are not ſo valuable as thoſe which are raiſed from ſeeds, becauſe the ſtock grows much faſter than the grafts; ſo that the lower part of the trunk, ſo far as the ſtock riſes, will often be twice the ſize of the upper; and if the trees ſtand much expoſed to the wind, the grafts are frequently broken off from the ſtock, after they are grown to a large ſize.

F. Paniculata is generally planted for ornament, the flowers making a fine appearance when they are in beauty, for almoſt every branch is terminated by a large looſe panicle; ſo that when the trees are large, and covered with flowers, they are diſtinguiſhable at a great diſtance.

All the other ſorts ſerve to make a variety in plantations, but have little beauty to recommend them; and as their wood ſeems to be greatly inferior to that of the common Aſh, there ſhould be few of theſe planted, becauſe they will only fill up the ſpace where better trees might grow.

DESCRIPTIONS, &c.

1. The Crown Imperial has a large round scaly root of a yellow colour, and a strong odour, of a fox; the stalk rises to the height of four feet or upwards; it is strong, succulent, and garnished two-thirds of the length on every side, with long narrow leaves ending in points, which are smooth and entire: the upper part, of the stalk is naked, a foot in length: then the flowers come out all round the stalk upon short foot-stalks, which turn downward, each sustaining one large flower. Above these rises a spreading tuft of green leaves, which are erect, and called the Coma. This plant flowers the beginning of april, and the seeds are ripe in july.

[Capsule a hexangular prism, the angles produced into wings; each wing scored on the outside with a deep broad furrow, and furnished with a double thick wing; on the inside a partition in the middle, to each side of which, the seeds are fixed horizontally, and ciliated on both edges of the future with white hairs like whiskers turned inwards *.]

The variety with yellow flowers, that with large flowers, and those with double flowers, are the most valuable; but that which has two or three whorls of flowers above each other, makes the finest appearance; though this seldom produces its flowers after this manner the first year after removing, but the second and third year after planting, the stalks will be taller, and frequently have three tier of flowers, one above another, which is called the Triple Crown. The stalks of this sort frequently run flat and broad, when they produce a greater number of flowers than usual: but this is only a luxuriancy of nature, not constant, though many of the writers have mentioned it as a particular variety.

As this is one of the earliest tall flowers of the spring, it makes a fine appearance in the middle of large borders, at a season when such flowers are much wanted to decorate the pleasure-garden; but the rank fox-like odour which they emit is too strung for most people, and renders the flowers less valuable than they would otherwise be.

[The beauty, however, of the plant, and the splendor of the magnificent pendulous flowers will ever secure this a place in large gardens and plantations. The singular nectary cannot but engage the attention of the curious observer: it is a white glandular cavity at the base of each petal, and has a drop of limpid nectareous juice standing in it, when the flower is in vigour. Another of the wonders of nature may be observed in the peduncles, which bend down whilst the plant is in flower, but become upright as the seed ripens. This circumstance, however, is by no means peculiar to this plant, but common to it with many others.]

* Gartner.

Varieties.

1. Common Crown Imperial, of a dirty red colour.

2. Yellow Crown Imperial, of a bright yellow. *Mill. fig. t.* 105.

3. Bright red Crown Imperial, called Fusai.

4. The pale yellow Crown Imperial.

5. The yellow striped Crown Imperial.

6. The large flowering Crown Imperial.

7. The broad-leaved late red Crown Imperial.

8. The double and triple crowned Imperial Crown.

9. The double red Crown Imperial.

10. The double yellow Crown Imperial.

11. The silver striped leaved Crown Imperial.

12. The yellow striped leaved Crown Imperial.

There are some few other varieties which are mentioned in the catalogues of the Dutch florists, but their distinctions are so minute that they are not distinguishable, so I shall pass them over, as those here inserted are all that I have seen growing either in England or Holland, which deserved any distinction.

[Introduced at Vienna in 1576.

Gerarde had great plenty of it in his garden in 1596; he calls it a rare and strange plant. Parkinson (in 1629) had not observed any variety in the colour of the flower. Lobel, however, enumerates many varieties.—It certainly came into these parts of Europe from Constantinople, but it is only conjectured by Clusius that its native country is Persia

The Crown Imperial has the same name in all the European languages; in German *Kaiserkrone*, in Danish *Keiserkrone*, in Swedish *Keijarkrona*, in French *la Couronne Imperiale* or *la Fritillaire Imperiale*, in Italian *la Corona Imperiale*, in Spanish *la Corona Imperial.*]

2. The Persian Lily has a large round root. Stem three feet high, the lower part closely garnished on every side with leaves, which are three inches long, and half an inch broad, of a gray colour, and twisted obliquely. Flowers in a loose spike at the top, forming a pyramid; they are shorter than the other sorts, spread wider at the brim, and are not bent down; they are of a dark purple colour, and appear in may, but seldom produce seeds in England.

[The lowest leaves grow in pairs, three or four together, opposite, in whorls †.

Root the size of an orange, of a taste extremely bitter, but without any remarkable smell ‡.

Supposed to be a native of Persia; and to have appeared in Europe in 1573. Gmelin found it in Russia. Cultivated here in Gerarde's garden 1596. In his herbal he says that it is a denizon in some few of our London gardens.—Parkinson (1629) informs us that it was sent unto us by the means of divers Turkey Merchants from Constantinople; and especially by the procurement of Mr. Nicholas Lete, a worthy merchant, and a lover of all fair flowers.]

β. The small Persian Lily, [which Mr. Miller makes a distinct species] has a much shorter stem, and smaller leaves; the stem branches out at the top into several small peduncles, each sustaining one dark-coloured flower.

3. The leaves of this are broader, and of a deeper green than the common Fritillary; the lower leaves are opposite, but those above alternate. Stem a foot and half high, terminated by two flowers of an obscure yellow colour, and spreading more at the brim than those of the common Fritillary, but turned downwards in the same manner. It flowers three weeks after that. It is a native of France and Russia.

4. [*Root* a solid bulb or tuber, about the size of a hazel nut, white or yellowish white, roundish, compressed, divisible into several, inclosed by the withered, wrinkled bulb of the preceding year, as

† Linn. spec. ‡ Bauh. hist.

in a caſe. *Stem* from ſix to twelve, fifteen and even eighteen inches in height, advancing conſiderably in length after flowering; it comes out from the ſide of the root, is ſimple, upright, round, ſmooth, glaucous, and not unfrequently purpliſh. *Leaves* three or four, ſometimes five or ſix, graſs-like, diſtantly alternate, half embracing, round on the under, and hollow on the upper ſide, ſomewhat twiſted and glaucous. *Flower* uſually ſingle, ſometimes two, or even three, on the top of the ſtem, large, pendulous, at firſt ſomewhat pyramidal, but afterwards bell-ſhaped; petals checquered with purple and white, or purple and greeniſh yellow; in our wild ones the colour is a dull red checquered with a deeper, but without mixture of either green or yellow; the three outer petals are gibbous at the baſe, the three inner plane: nectary narrow, greeniſh, fleſhy and glandular, connecting the filaments to the petals: filaments twice the length of the germ; anthers flatiſh, with four grooves, and a greeniſh point at the top of each, two-celled, nearly as long as the filaments, becoming ſhorter by one half on the ſhedding of the pollen: germ ſcarce manifeſtly three-cornered; ſtyle downy, round, a little thickened above, divided into three ſegments, which are round, diverging, and marked both within and without with a groove, viſible by a magnifier; ſtigmas ſimple villoſe: capſule a priſm of three blunt corners[c],] not pendulous, but erect.

Native of the ſouthern countries of Europe. [Found alſo in a wild ſtate near Upſala in Sweden, but eſcaped from a garden. In England it was firſt mentioned by Mr. Blackſtone to grow in Mawde fields near Riſlip common, Middleſex, and to have been obſerved there by Mr. Aſhby, of Breakſpears, above forty years. It has ſince been found between Mortlake and Kew, near Enfield, in a wood near Bromley in Kent; near Bury St. Edmunds, and between Laxfield and Stirrup-Street, in Suffolk; Weſthoe near Linton in Cambridgeſhire; near Leiceſter; and in a meadow near Blymhill, in Staffordſhire.

It flowers in april and may, and if the ſeaſon be mild, at the beginning of the former month, or even the end of march.

The common Fritillary is named in German *Kiebitzey*, in Dutch *Kiewitseloem*, in Daniſh *Vibeeg*, in Sweditſh *Vipaägg*, in French *la Fritillaire Meleagre* or *Panachee*, *le Damier*, in Italian *Fritillaria*, *Giglio variegato*, *Meleagride*. *Fritillaria ſcacchegiata*, in Spaniſh *la Fritillaria*, *el Meleagro*.

Gerarde calls it *Turkey-hen* or *Guinea-hen flower*, and *Checkered Daffodill*. The curious and painful herbariſt of Paris, John Robin, ſent him many plants for his garden, where they proſpered (as he informs us) as in their own native country; and were then greatly eſteemed for the beautifying of our gardens, and the boſoms of the beautiful.

Some call it, ſays Parkinſon, *Narciſſus Caparonius*, from the firſt finder *Noel Caparon*, an Apothecary then dwelling at Orleans, but ſhortly after murdered in the maſſacre of France. He leaves it to every one's will, to call it in Engliſh either *Fritillaria*, as it is called of moſt, or *checkered Daffodill* or *Guinea-hen flower*; or, as he does, *checkered Lilly*. Lobel makes it a kind of *Tulip*. The country people about Riſlip call the flowers *Snake's-heads*.

Many varieties have been ſent from Spain, Portugal, Italy, &c. The moſt remarkable of theſe are here recited.] Many others have been raiſed from ſeed by the florifts, which differ in the ſize and colour of their flowers; theſe amount to a conſiderable number in the catalogues of the Dutch florifts: but as new varieties may be continually produced, and theſe flowers are no longer in ſuch eſteem as they were formerly, it would be to little purpoſe to enumerate them.

[Parkinſon (*Parad.* 2. 1629) has twelve varieties. —1. The Common purple Fritillary. 2. Blood-red. 3. Great purple or red. 4. White. 5. Double bluſh. 6. Pure yellow. 7. Checkered yellow. 8. Great yellow Italian. 9. Small Italian. 10. Small yellow of Portugal. 11. Black. 12. Spaniſh black.

Johnſon in Gerarde (a. 1636.) has thirteen, ſome of them different from Parkinſon's.

Ray (a. 1688) enumerates twelve, chiefly from Parkinſon and the two brothers, John and Caſpar Bauhin.]

Mr. Miller reckons as diſtinct ſpecies, beſides 1. *a.* the common early purple; of which there is a variety with a double flower. 2. *b. The Black* (*n.* 3.) ſeldom riſing more than a foot high, the leaves ſhorter than in the foregoing, each ſtalk terminated by three or four flowers, riſing above each other, of a dark purple colour, with yelloviſh ſpots; and flowering three weeks later than the common purple. 3. *c. The great yellow Italian*, about a foot high, with ſpear-ſhaped leaves four inches long and one broad, ſometimes oppoſite but generally alternate; the ſtem terminated by one large flower of a yelloviſh colour, checquered with light purple, and flowering the beginning of april. There are two or three ſubordinate varieties of this, which differ in the ſize and colour of their flowers, and the breadth of their leaves. 4. *d. Umbellate Fritillary*, a foot and half high, with ſhorter and broader leaves, of a grayiſh colour; the flowers produced round the ſtalks like thoſe of the Crown-Imperial, of a dark purple colour, checquered with a yelloviſh green. This flowers three weeks later than the common purple.

[He does not mention the *white*, (*n.* 7.) which ſometimes is almoſt without any ſpots or marks; theſe, however, are frequently viſible enough, and in ſome flowers again a faint bluſh-colour may be obſerved.

5. Stem annual, quite ſimple, hard, ſlender, round, upright, a foot and half high. Leaves ſmooth, quite entire, rounded at the baſe, then conical, with a long point. Flowers pendulous, the whole duſky purple, and without ſmell. Corolla thick, ſix-cornered, almoſt cloſed. Style trifid, with ſimple ſtigmas. In colour it agrees with Fr. ſerotina atro-purpurea of Bauhin's pinax, 64. *n.* 8;—in the varying ſituation of the leaves with Fr. pyrenaica of Linneus; but it is a different ſpecies from both. Cultivated about Canton in China[*].]

PROPAGATION AND CULTURE.

1. This may be propagated by ſeeds, or offſets from the root; the firſt is too tedious for moſt of the Engliſh florifts, becauſe the plants ſo raiſed are ſix or ſeven years before they flower; but the Dutch and Flemiſh gardeners, who have more patience, frequently raiſe them from ſeeds, ſo get ſome new varieties, which reward their labour. The method of propagating theſe flowers from ſeeds being nearly the ſame as for the Tulip, the reader is deſired to turn to that article, where there are full directions for performing it.

The common method of propagating them here, is by offſets ſent out from the old roots, which will flower ſtrong the ſecond year after they are taken from the roots; but in order to have plenty of theſe the roots ſhould not be tranſplanted oftener than every third year, by which time each root will have put out ſeveral offſets, ſome of which will be large enough to flower the following year, ſo may be planted in the borders of the flower-garden, where they are to remain; and the ſmaller roots may be planted in a nurſery-bed, to grow a year or two according to their ſize; therefore they ſhould be ſorted, and the ſmalleſt roots planted in a bed together, which ſhould remain there two years, and the larger by themſelves to ſtand one year, by which time they will have acquired ſtrength enough to flower, ſo may then be removed into the pleaſure garden.

The time for taking up theſe roots is in the beginning of july, when their ſtalks will be decayed;

[c] Curtis, Woodw. Mſſ. Withering.

[*] Loureiro.

and they may be kept out of the ground two months but they ſhould be laid ſingle in a dry ſhady room, but not in heaps, or in a moiſt place, which will cauſe them to grow mouldy, and rot. The off-ſets ſhould be firſt planted, for as theſe are ſmall, they will be apt to ſhrink if they are kept long out of the ground.

As the roots are large, they muſt not be planted too near other flowers; and when they are planted in beds by themſelves, they ſhould not be nearer than a foot and a half in the rows, and two feet row from row; they ſhould be planted ſix inches deep at leaſt, eſpecially the ſtrong roots: they delight in a light ſoil, not too wet, nor very full of dung, therefore if any dung is laid upon the borders where they are planted, it ſhould be buried pretty deep, ſo as to be two or three inches below the roots.

2, 3, 4. Theſe plants are propagated either by ſeeds, or off-ſets from the old roots; by the firſt of which methods new varieties will be obtained, as alſo a larger ſtock of roots in three years than can be obtained in twenty or thirty years in the latter method: I ſhall therefore firſt treat of their propagation by ſeeds.

Having provided yourſelf with ſome good ſeeds, ſaved from the faireſt flowers, you muſt procure ſome ſhallow pans or boxes, which muſt have ſome holes in their bottoms to let out the moiſture; theſe you ſhould fill with light freſh earth, laying a few potheards over the holes, to prevent the earth from ſtopping them; then, having laid the earth very level in the boxes, &c. you muſt ſow the ſeeds thereon pretty thick, covering it with fine ſifted earth a quarter of an inch thick. The time for ſowing the ſeed is about the beginning of auguſt; for if it be kept much longer out of the ground, it will not grow; then place the boxes or pans where they may have the morning ſun until eleven o'clock, obſerving, if the ſeaſon proves dry, to water them gently, as alſo to pull up all weeds as ſoon as they appear; for if they are ſuffered to remain until they have taken deep root into the earth, they would draw the ſeeds out of the ground whenever they are pulled up. Toward the latter end of ſeptember you ſhould remove the boxes, &c. into a warmer ſituation, placing them cloſe to a hedge or wall expoſed to the ſouth; if they are ſown in pots, theſe ſhould be plunged into the ground, but they are beſt in tubs; theſe ſhould be covered in ſevere froſt. In this ſituation they may remain until the middle of march, by which time the plants will become up an inch high; you muſt therefore remove the boxes, as the weather becomes hot, into a more ſhady ſituation; for while the plants are young, they are liable to ſuffer by being too much expoſed to the ſun: and in this ſhady ſituation they may remain during the heat of the ſummer, obſerving to keep them clear from weeds, and to refreſh them now and then with a little moiſture; but be careful not to give them much water after their leaves are decayed, which would rot their roots. About the beginning of auguſt, if the roots are very thick in the boxes, you ſhould prepare a bed of good light freſh earth, which muſt be levelled very even, upon which you ſhould ſpread the earth in the boxes in which the ſmall roots are contained, equally covering it about one-fourth of an inch thick with the ſame freſh earth: this bed ſhould be ſituated in a warm poſition, but not too cloſe to hedges, walls, or pales, which would cauſe their leaves to be long and ſlender, and make the roots weaker than if placed in a more open expoſure.

In this bed they may remain until they flower, which is generally the third year from ſowing; at which time you ſhould put down a mark to the roots of all ſuch as produce fair flowers, that at the time of taking them out of the ground, which ought to be ſoon after their green leaves are decayed, they may be ſelected into a bed amongſt your old roots of this flower, which, for their beauty, are preſerved in the beſt gardens; but the other leſs valuable flowers may be planted in the borders of the parterre-garden for their variety, where, being intermixed with other flowers of different ſeaſons, they will make a good appearance.

The fine ſorts of this flower ſhould remain undiſturbed three years, by which time they will have produced many off-ſets; and ſhould be taken up when their leaves are decayed, and planted into a freſh bed, taking ſuch of their off-ſets as are large enough to produce flowers to plant in the flower garden; but the ſmaller roots may be planted into a nurſery-bed until they have obtained ſtrength enough to flower; but you muſt never ſuffer theſe roots to lay out of the ground when you remove them, but plant them again immediately, otherwiſe they will periſh.

During theſe three years which I have adviſed the roots to remain in the beds, the ſurface of the earth ſhould be ſtirred every autumn with a trowel, obſerving not to go ſo deep as to bruiſe the root, and at the ſame time lay a thin cover of very rotten dung or tanners bark upon the ſurface of the beds; which, being waſhed into the ground, will cauſe the flowers to be larger, as alſo the roots to make a greater increaſe; you muſt alſo obſerve to keep them conſtantly clear from weeds, and thoſe roots which you would preſerve with care, ſhould not be ſuffered to ſeed.

When a ſtock of good flowers are obtained, they may be preſerved and increaſed in the ſame manner as other bulbous rooted flowers, which is by off-ſets ſent out from their roots, which ſhould be taken off every other year from the fineſt ſorts; but the ordinary flowers may remain three years undiſturbed, in which time they will have multiplied ſo much, as that each root will have formed a cluſter; ſo that if they are left longer together, the roots will be ſmall, and the flowers very weak; therefore, if theſe are taken up every other year, the roots will be the ſtronger. Theſe roots may be treated in the ſame manner as Tulips, and other bulbous rooted flowers, with this difference only, that the roots will not bear to be kept out of the ground ſo long; therefore if there ſhould be a neceſſity for keeping them out of the ground any time, it will be beſt to put the roots into ſand to prevent their ſhrinking.

As theſe flowers come out early in the ſpring, they make a pretty appearance in the borders of the pleaſure garden, where they are planted in ſmall clumps; for when they ſtand ſingle in the borders, they make but a poor figure.

DESCRIPTIONS, &c.

1. Root woody, branched, reddish. Stem herbaceous, upright, quite simple, reddish green, leafy, two feet high at most. Leaves lanceolate, entire, pale green, a little firm or coriaceous, sessile, disposed in threes. Peduncles one-flowered, scattered, and forming a straight terminating raceme. Flowers large, very fine, of a very bright scarlet, having eight stamens, not projecting beyond the flower; and the berry is a little larger than an olive, fleshy, soft, reddish black, somewhat pubescent, of a very pleasant taste; the seeds are small and brown. Plumier observed this plant in St. Domingo [a], and it was afterwards found by Dr. Houstoun at Carthagena in New Spain, whence he sent the seeds into England, [it must have been cultivated here therefore by Mr. Miller before 1733, in which year Dr. Houstoun died.

2. This is a shrub, growing to the height of six or seven feet. The leaves are commonly opposite, on short petioles, of a fine green, having the veins tinged with red, with a fine down on them. Peduncles axillary, one-flowered, longer than the leaves. Flowers pendulous, bright scarlet, with a four-parted calyx, four petals, and eight stamens.

Scarlet Fuchsia is a plant of peculiar beauty, producing its rich pendant blossoms through most part of the summer: the petals in the centre of the flower are particularly deserving of notice; they somewhat resemble a small roll of the richest purple-coloured ribband [b].

It is a native of Chili, and was introduced into the royal garden at Kew in 1788, by Captain Firth. It flowers from may to july [c]. Mr. Lee of Hammersmith is said to have had this plant first for sale [d].

3. This was found in South America by Mutis.

4. This is a very smooth tree. Leaves on long petioles, hoary underneath, very finely serrate. Flowers pendulous, very large. Germ oblong. Corolla funnel-shaped; tube globular at the base, then cylindric, and gradually widening into the border, which is eight-cleft, four of the alternated segments lanceolate, spreading, the other four one-third only the size of the others, and erect [e].

According to Forster, there is no corolla, except four nectaries, which are ovate-lanceolate, erect, interposed between the segments of the calyx, and only one-third of their size. Others call these the petals. The tube of the calyx is callous at the base, and curved in a little; the segments lanceolate, horizontal, only half the length of the tube. Filaments eight, the length of the broder: anthers orbiculate, fastened by the back to the filaments. Style filiform, erect, longer than the calyx. Stigma globular, tubercled. Capsule (Berry [f]) oblong.
Native of New Zealand. Forster gave it the name of *Skinnera* from Mr. Skinner of Oxford—"acutissimo oculatissimoque botanico Oxoniensi," as he expresses it [g].

5. Native of Jamaica [h].]

PROPAGATION AND CULTURE.

1. This is propagated by seeds, which must be sown in pots filled with rich light earth, and plunged into a hot-bed of tanner's bark, and treated in the same way as other seeds from warm countries. In about a month or six weeks after the seeds are sown, the plants will begin to appear, when they should be carefully cleared from weeds, and frequently refreshed with water to promote their growth; and when they are about two inches high, they should be shaken out of the pot, and separated carefully; then plant each into a small pot filled with light rich earth, and plunge them again into a hot-bed of tanner's bark, being careful to screen them from the sun until they have taken new root; after which time they must have fresh air admitted to them every day in proportion to the warmth of the season, and should be frequently watered. As the season advances and becomes warm, the glasses of the hot-bed should be raised higher, to admit a greater share of air to the plants, to prevent their drawing up weak; and when the plants are grown so tall as to reach the glasses, they should be removed into the bark-stove, and plunged into the tan-bed. In winter these plants require to be kept very warm, and at that season they must not have much water, but in summer it must be often repeated.

These plants are too tender to thrive in the open air in this country, even in the hottest part of the year; therefore they should constantly remain in the stove, observing to let in a large share of fresh air in summer, but in winter they must be kept warm; with this management the plants will produce their flowers, and make a beautiful appearance in the stove, amongst other tender exotic plants.

[The second species, which we now have in our stoves, if it be really different from the first, may however be treated in the same manner.

Though it will not succeed well in the winter, nor be easily propagated unless in a stove, yet it will flower very well during the summer months, in a good green-house or hot-bed frame. It is easily increased by layers and cuttings, as well as seeds [i].

FUCOIDES. See *Fucus.*

FUCUS (*of Pliny. Hence* fucare, *to dye or paint, some of the Fuci or Sea-weeds being used for this purpose.*)
Class. 24. 3. Cryptogamia Algæ.
Lin. gen. n. 1205. *Schreb.* 1671.

GENERIC CHARACTER.

MALE. *Vesicles* smooth, hollow, with villose hairs within, interwoven.

FEM. *Vesicles* smooth, filled with gelly, sprinkled with immersed grains prominent at the tip. *Seeds* solitary.

This genus comprehends most of those plants which are commonly called *Sea weeds.* Fifty-eight species are enumerated in the fourteenth edition of Systema Vegetabilium.—Sixty-eight British species, besides many varieties, are enumerated in Dr. Withering's Botanical Arrangements.

They may all be used to manure land, or they may be burnt to make kelp, which is an impure fossil alkali. Many of them make very beautiful specimens for the herbarium, and are often seen disposed on paper so as to form a sort of picture.

Some of the species are eaten, either fresh out of the sea, or boiled tender, with butter, pepper and vinegar: as *Fucus saccharinus, digitatus, palmatus,* &c. If the first of these be washed in spring water, and then hung up in a warm place, a substance like sugar exsudes from it. The last is called by the

DESCRIPTIONS, *&c.*

[The leaves are many-parted, ſometimes biternate, and the end of the rachis cirrhoſe. The flowers are in terminating ſpikes[a].

In their flower and fruit they have a great affinity with papilionaceous plants, although that affinity is not very obvious at firſt ſight: and ſome parts of the ſtructure are peculiar to the genus. Thus the poſterior part of the corolla terminates in a nectary like that of the Violet. But the part in which Fumitory differs moſt from the papilionaceous flowers is the calyx, which conſiſts of two ſmall lateral leaves, more like ſtipules. The ſeed-veſſel in ſome ſpecies has not much reſemblance to thoſe of the papilionaceous tribe; and hence Ray divided the genus[b].]

1. Root ſcaly, the ſize of a large hazel nut. Flower-ſtalk eight or nine inches high. [Root-leaves in pairs, triternate, gaſhed, ſmooth, ſlender; with red petioles. Scape ſimple, round, length of the leaf, rufous. Raceme terminating, ſimple, the flowers (four or five) pendulous; pedicels one-flowered, with a pair of bractles to each, oppoſite, ovate, ſharp, red, ſmall, approximating to the flower: calyx ovate, preſſed cloſe, ſmall, white: corolla white; border yellow, two-lipped: lips equal, concave, reflex, ovate, entire; throat cloſed, yellow, the ſides widened at the edge, and moiſtened with nectareous juice: ſpurs equal, diſtant, ſomewhat compreſſed, nearly the length of the corolla: filaments on each ſide three diſtinct. Native of Virginia and Canada. Perennial[c]. It flowers in June and July; and was cultivated by Mr. Miller in 1759[d].

2. This is a fine plant, with very large, handſome flowers. It has the air of *F. bulboſa*, but is bigger in all its parts. The branches proceed from the axils of the leaves, and are but few. Stem erect. The raceme has no bractles. The corolla is the ſize of the laſt joint of the thumb, divided at the back of it into two equal rounded lobes. Native of Siberia[e].

3. Annual.—Native of North America. It flowers from June to ſeptember. Introduced about 1778, by John Fothergill, M. D.[f].

[a] Juſſieu. [b] Curtis. [c] Linn. mant.
[d] Hort kew. [e] Linn. ſpec. [f] Hort. kew.

4. Peren-

4. Perennial. Very like the next ſpecies, but much larger. Root-leaves ſeven to nine, a ſpan in length, bipinnate. Scapes one or two, oblique, five-cornered. Stem-leaves four, ſeſſile, compound. Raceme very blunt; the flowers directed one way. Bractes ovate-lanceolate, entire. Flowers double the ſize of thoſe in *F. bulboſa*, white, with a yellow border, ſmelling like Cowſlips; the lips neither emarginate nor ſerrate; throat black at the tip; calyx minute, toothed[s]. Capſule when ripe herbaceous, thin, friable. Seed large, lenticular-beaked, very ſmooth, dark and ſhining[t]. Native of Siberia.—It flowers in may. Introduced 1783, by Mr. John Græfer[l].

5. Theſe plants are united ſpecifically by a fleſhy, ſimple root. In variety β. the plants of the firſt year produce entire bractes, which in the following ones become cloven. Buds radical, two, three-valved. Stem ſimple, ſomewhat angular, with a ſingle branch; ſtructure of the leaves decompound; raceme terminating, ſolitary, with bractes between the flowers. Calyx and corolla, &c. very ſmall[x].

α and β, according to Reichard, are two diſtinct ſpecies, not altered by culture. γ. belongs to α, the roots being indifferently hollow or ſolid: α alſo varies with a white flower.

Linnæus informs us that the three varieties are all natives of Sweden, but in different provinces; the firſt in Scania, both with a red and a white flower; the ſecond in moſt of the woods of Upland; and the third on the coaſts of Roſlag and Finland.—They may be thus diſtinguiſhed—α has a hollow root, and entire bractes; β a ſolid root, and entire bractes; γ a ſolid root, and gaſhed bractes: the hollow and ſolid-rooted Fumitory never are ſeen together, for they affect different ſoils; the former flowers fourteen days later, and the latter has entire bractes the firſt year. But there are many characteriſtic and eſſential marks common to them all, which are hardly to be found in the other ſpecies of this genus. Thus the calyx in theſe is ſcarcely viſible to the naked eye: the root is a bulb, fibrous at bottom, gemmiparous at top: the ſtem is ſimple without branches, except that a ſingle one ſometimes comes out from the uppermoſt ſcale of the bud: there are commonly two or three leaves on the ſtem: there is a gemmeous membrane from the root, incloſing the plant before it unfolds: and laſtly, a broad leafy bracte under each flower[l].

Others make only two varieties, or perhaps ſpecies, ſuppoſing that α and β are one and the ſame: the root at firſt nearly globular, ſolid, and putting forth fibres from every ſide; becoming afterwards hemiſpherical, and hollow underneath; only two leaves on the ſtem; bractes quite entire, ſhorter than the flowers; corollas either white or purple.—γ. The other has the bulb of the root ſmaller, always ſolid, and obovate, putting forth fibres only at the baſe; leaves more numerous, (four to ſix) uſually more tender and narrower; bractes cloven like parallel fingers, the length of the flowers; corollas purple, ſmaller than the others; and the whole plant lower. Tranſplanted into a garden with the former, it did not in ten years acquire any hollowneſs in the root, nor did the cloven bractes ever become entire[m].—According to Curtis, the ſolid-rooted Fumitory rarely exceeds three or four inches in height, and produces its ſpike of purple flowers in april; it does not vary very much in colour. The hollow-rooted Fumitory has a much larger root, hollow like a ſhell; the plant grows to twice the ſize of the other, and bears a foliage and flowers proportionably larger; the bractes, which in that aſſume a kind of fingered appearance, in this are entire, or but ſlightly indented; and it flowers about three weeks earlier. There are three principal varieties of it in point of colour—white, bluſh-coloured and purple.

[As this ſpecies is found in moſt parts of Europe from Sweden to Italy, Linnæus remarks, as a ſingularity, that it does not grow wild in England. But the ſolid variety has been found in Weſtmoreland and near Birmingham. I gathered the hollow-rooted variety in Savoy on the 15th of march, 1773, in flower. In our gardens they appear early in april. Cultivated in 1596, by Gerarde[n].

Mr. Miller ſays that the ſolid-rooted Bulbous Fumitory is common in many of our old gardens, but that the hollow-rooted one is now rarely to be found in them. He gives them as diſtinct ſpecies.

6. Annual. Stem upright, a foot and half high, round, and very ſmooth, ſending out ſeveral branches at top. Leaves ſmooth, branching, pale, divided like the common ſort, but the leaflets larger and more obtuſe. Flowers in looſe panicles from the ſides of the ſtem, and at the extremities of the branches, of a pale purple colour, with yellow chaps or lips. Pods taper, narrow, an inch and half long, containing many ſmall black ſhining ſeeds. It flowers during ſummer.

[Native of North America. Cultivated in 1683, by Mr. James Sutherland[o].

7. This is very like the ninth ſpecies, but it is perennial. The ſpur of the corolla is rounded, and ſhorter by half than the tube. The racemes have no bractes[p].]

Mr. Miller adds, that the ſtalks of this have blunt angles, whereas thoſe of the ninth are acute; that they are of a purpliſh colour; and that the flowers grow in a looſer panicle, on longer pedicels.

[The root ſtrikes deep into the ground. Stems many, ſucculent, diffuſed, about ſix inches high. Leaves on long, branching petioles, compoſed of many irregular leaflets, trifid at the top. Peduncles axillary, naked, longer than the leaves, ſupporting eight or nine flowers, of a bright yellow colour, in a looſe ſpike. The leaves continue green all the year, and the flowers in ſucceſſion from april to october; ſo that this ſpecies deſerves a place in every garden. It is peculiarly proper for rock-work, old walls and buildings, in which the ſeeds often lodge of themſelves, being thrown to a conſiderable diſtance by the elaſticity of the pods[q].

Native of Barbary. Caſtleton, Derbyſhire. Fountain's Hall. Cultivated 1596, by Gerarde[r].

8. Annual. Stems herbaceous, branching, five-cornered, brittle. Leaves alternate, ſuper-decompound, with oblong leaflets. Flowers yellow. Pods oval, compreſſed, ſmooth, ſomewhat elaſtic. Native of Siberia[s].

9. Annual. Stem four-cornered at the baſe. Leaves ſuperdecompound, the terminating leaflets larger, and ſemitrifid; the middle ſegment lobed; petioles three-cornered. Racemes naked. Pedicels ſhorter by half than the corollas, blackiſh at the tip. Corollas whitiſh, with the wings yellow at the tip, and drawn to a point; filaments two, with two anthers only on each, cloſe to the ſtigma when in full perfection, and full of orange-coloured pollen: ſtyle cylindric, ſlender, with a bent ſtigma[t].

There is a ſucceſſion of the flowers from may to october: and this, as well as the ſeventh, is proper for walls, old buildings and rock-work.—Native of the South of Europe. Cultivated in 1596, by Gerarde[u].]

10. This has weak trailing ſtems, which are much divided, and leaflets divided into three parts, each of which has three heart-ſhaped lobes; the flowers are produced in ſmall looſe panicles from the ſide of the ſtalks; they are of a greeniſh white, and appear moſt of the ſummer months.

Native of Spain and Italy, upon old walls and in rocky places.

11. [*Root* annual. *Stems* from nine to ſeventeen inches in height, ſpreading, angular, enlarged at the joints, branched, ſmooth, tender, and ſomewhat

flexuoſe.

flexuose. *Leaves* alternate, petioled, glaucous, smooth, somewhat fleshy, superdecompound, the last division bifid or trifid,[r] the extreme segments lanceolate. *Flowers* alternate, in very long spikes, on very short pedicels, under each of which is a lanceolate, membranaceous bractle, purple at top. The calyx has little teeth about the edges. Corolla reddish, tipped with deep purple, sometimes pale purple or white[s].

It is a common weed in corn fields, gardens, and on ditch banks; flowering from april to auguſt and even later.

Kine and sheep eat it: to the latter it is accounted salubrious.

The leaves are succulent, saline and bitter. The expressed juice in doses of two or three ounces, with whey is useful in hypochondriacal, scorbutic and cachectic habits. It corrects acidity, and strengthens the tone of the stomach. Hoffman prefers it to all other medicines as a sweetener of the blood. There is no doubt of its utility in obstructions of the viscera, and the diseases arising from them. The celebrated Boerhave frequently prescribed it in the black jaundice and bilious cholics. An infusion of the leaves is used as a cosmetic to remove freckles, and clear the skin; and Dr. Cullen has experienced its good effects in many cutaneous disorders, which may be called *Lepra*[t].

12. This seems to be nothing more than a variety of the foregoing. Mr. Hudson can perceive no difference except in the colour of the flowers, which in this is white with a purple tip. It climbs, not by tendrils, but by the bending or twisting of the petioles, but Louis Gerard attributes this wholly to its situation in hedges or among bushes. Dr. Stokes however has observed the stem sometimes trailing, and interweaving its branches among the grass, very much branched, sometimes three feet long, the blossoms pale red. The stems are longer and weaker; the leaves more distant, and not so finely divided, the extreme divisions broader and blunter than the foregoing: the spikes of flowers are on longer pedunckes, but with fewer flowers on a spike[u]. All these differences may also be owing to situation.

Krocker has described this plant very minutely, and says particularly that the stems are remarkably weak, and the ends of the branches finer than a bristle, that the case is the same with the petioles and rachis of the leaves, and peduncles of the flowers; that these fine extremities twist about neighbouring shrubs, grass or other plants, and keep such fast hold as to be separated with difficulty; but that real tendrils are seldom or ever to be found, or if there be any such, they are very short, weak and useless. Considering that the substance of the whole plant is more tender than in the foregoing; the stem more diffused, twisting at the extremities, and never standing erect of itself; the racemes almost always lateral and very short; the flowers very small, whitish, and green only at the tip; the partial peduncles thicker than the common ones; the leaves on longer petioles, larger and more tender, with their rachis or common petiole twisted and doing the office of tendrils, and even sometimes terminating in real tendrils; he is rather inclined to think that this is a distinct species. It differs from *F. claviculata* in the absence of genuine tendrils; and in having three-lobed leaves, the lobes bifid or trifid; whereas those of *F. claviculata* are pinnate, the pinnas entire, and smaller than in this species.

Native of Provence, Silesia, and Britain. Linneus remarks as a singularity, that this does not occur in Sweden, where the foregoing is very common, not only in corn fields, but among bushes.]

13. Annual. The stalks more erect than in the common sort; the leaves are very finely divided, and the flowers grow in a loose spike; they are of a deep red colour, and appear about the same time.

[The flowers grow very close together in the spike; and the leaves are glaucous[x].

This plant is minutely described by Ray, who was well acquainted with it in its place of natural growth. —Root slender, simple, white, straight, with few fibres, bitter and hot. Stems many, the middle one larger and firmer than the rest, about nine inches in height, streaked, hollow. Spikes of flowers short and thick, opening one after the other from the bottom upwards, beautiful with a variety of colours, light and dark purple, greenish yellow, white and flesh-colour. Seeds flatted like those of flax, smooth and shining. The leaves are smaller than in the other species, like Camomile: those that proceed from the root are on longer petioles, but the segments are shorter: those on the stem have shorter petioles but longer segments. Both stems and leaves are covered with a glaucous bloom. There is little or no bitterness in the leaves.

Linneus suspects that this may be a hybridous plant; and is of opinion, that whoever shall determine this and the following to be varieties of the 11th or common Fumitory can hardly err; the fruit indicating that they are one and the same.

Native of Spain, Portugal, Italy, and the South of France.—Cultivated here in 1714[y]. It flowers with us in july and auguſt. Ray says it flowers in summer, whereas Linneus asserts that the flowers are vernal.

14. *Root* annual. *Stems* three-cornered, slender, and unable to support themselves, purplish at the base. *Leaves* glaucous, paler beneath, pinnate, terminated by branched tendrils; leaflets two to five, inversely ovate, ovate-lanceolate or Lanceolate, ending in a sharp flexible point, alternate, petioled. *Flowers* few (about five, seldom more than two coming to perfection) in short terminating spikes, corolla pale, greenish white or straw coloured. Seeds generally three, in oblong, pointed, smooth pods[z].

Native of Denmark and Britain, in woods and moist hedges, boggy and rocky places in a sandy soil, on the banks of lakes and rivers, and on the thatch of cottages. As on Bleakheath and about Charlton and Greenwich. At Snaresbrook near Woodford, Essex. On the banks of the Trent near Ouseley in Staffordshire. In the hedges between Bala in Merionethshire and Pimble-mear. Above Great Malvern tower. About Birmingham. Rocks of Stonehall, near Rawdon, seven miles from Leeds. Thorpe near Norwich. In the quarries at Inner-Keith, in Scotland. Near Whitwick in Leicestershire. Kendal in Westmoreland. Flowering from the end of may to the end of july.]

15. This is an annual plant, with trailing stalks, which are two or three feet long, dividing into many smaller ones, with small branching leaves, like those of common Fumitory, but ending in tendrils. Flowers in loose panicles, from the side of the stalks, of a whitish yellow colour.

[The terminating leaflets are protracted into tendrils. Peduncles opposite to the leaves, bearing one to four flowers. Siliques ovate, large, inflated, pendulous—or rather, lanceolate, covered with a hollow, berried pericarp[a].

It is thus, more accurately, described by Gærtner: Pericarp double, composed of the rind or outer involucre, arising from the germ itself, and of the capsule within the involucre. Involucre large, somewhat leathery, inflated, globular, acuminate at the end, two-valved; the valves cohering with the capsule by means of a thready cellular substance. Capsule placed in the axis of the involucre, oblong, acuminate to both ends, a little flatted, membranaceous in the middle, very thin, diaphanous, but at each side thickened, suberous, opake, one-celled, valveless, bursting irregularly by the involucre when it opens. Seeds numerous rounded-kidney-form, towards the navel slightly flatted, dark-coloured,

very

very ſmooth and ſhining, fixed to the thickened edges of the capſule.

Native of the Cape of Good Hope. Cultivated in the Cheſſea garden, in 1696. It flowers in july [a].]

PROPAGATION AND CULTURE.

1. This is propagated by offſets from the root; it loves a ſhady ſituation and a light ſoil; the beſt time to tranſplant the roots is in autumn, when the leaves are decayed, for it ſhoots pretty early in the ſpring, therefore it would not be ſafe to remove them at that ſeaſon.

4, 5. Are propagated by offſets, as other bulbous-rooted flowers; theſe are very pretty ornaments to borders in a ſmall flower-garden. They are extreme hardy, but do not increaſe very faſt, ſeldom producing ſeeds with us; and their bulbs do not multiply very much, eſpecially if they are often tranſplanted. They love a light ſandy ſoil, and ſhould be ſuffered to remain three years undiſturbed, in which time they will produce ſeveral offſets. The beſt ſeaſon for tranſplanting them is from may to auguſt, when the leaves begin to die off; for if they are taken up when the leaves are freſh, it will greatly weaken their roots.

6, 7, 8, 9, 10, 12, 13, 14. If the ſeeds of theſe are permitted to ſcatter, the plants will come up without any trouble, and require no other care but to thin them where they are too cloſe, and to keep them clean from weeds.

Theſe thrive beſt on old walls and buildings and on rocks; they ſcatter their ſeeds from their elaſtic pods, and require no care in the cultivation.

11. Is a common weed in gardens.

15. This is propagated by ſeeds, which ſhould be ſown upon a moderate hot-bed in the ſpring; and when the plants are fit to remove, they muſt be each planted in a ſmall pot filled with light earth, and plunged again into the hot-bed, where they muſt be ſhaded from the ſun till they have taken new root; after which they ſhould have a large ſhare of air admitted to them at all times in mild weather, to prevent their drawing up weak; and as ſoon as the ſeaſon is favourable, they ſhould be inured to bear the open air, to which they may be removed the beginning of june, when they may be ſhaken out of the pots, preſerving all the earth to their roots, and planted in a warm border, where their ſtalks ſhould be ſupported with ſticks to prevent their trailing on the ground; and in july the plants will flower, and continue a ſucceſſion of flowers till the froſt deſtroys the plants; the ſeeds ripen in autumn.

FUMARIA BULBOSA. See *Adoxa*.

FUMITORY. See *Fumaria*.

——, Bulbous. See *Adoxa*.

FUNARIA. A genus of Moſs. *Schreb. gen. n.* 1650. The ſame with *Koelreutera* of Hedwig, *fund.* 2. 95. It contains ſome of Linneus's *Mniums*.

FUNGI. (*Fungus* from σφογγος, on account of its ſpongy nature.) *Muſhrooms.*—Cryptogamia Fungi, the laſt order in the laſt claſs of Linneus's ſyſtem, and kept together as one claſs under every arrangement.

We know ſo little yet about the fructification of Funguſſes, that we are obliged to take the characters from the general external form. It is evident, that they are vegetables, and produce ſeed, by which they have been propagated, and they ſeem to belong to the claſs Monoecia. Hedwig has made ſome important diſcoveries reſpecting the fructification of Funguſſes, by the uſe of high magniſiers; and thinks he has diſcovered ſtamens in the threads which appear on the edge of the cap or pileus, on the membrane or volva, or on the ſtem itſelf. The ſeeds are a dark powder in the gills of the Agarics; in the Boleti the ſeeds are within the membrane that lines the tubes; in Peziza cyathoides they appear to be incloſed in a ſort of pod. The black powder in the Lycoperdon and Mucor was taken for animalcules by Baron Munckhauſen, and thus the Fungi were on the verge of migrating into the claſs of Zoophytes. According to the Baron, theſe globules, which appear black, are ſemitranſparent, and contain a black particle. If they be mixed with water and kept in a warm place, they preſently ſwell, and are changed into ovate animalcules, that in a few days unite and form a maſs of a pretty firm texture, which is the Fungus.

Mr. Ellis however has ſhewn ſatisfactorily that the motion of theſe globules was occaſioned by a number of very minute animalcules feeding upon them, and theſe being much ſmaller than the globules, are difficult to detect, on which account the Baron ſeems to have overlooked them [b].

Many of the Fungus tribe are much eſteemed in foreign countries as a luxurious food, on account of their high flavour. We in England almoſt confine ourſelves to the Agaricus campeſtris, which we call excluſively Muſhroom, the Morell, and the Truffle; which are particularly treated of under the article AGARICUS, PHALLUS, and LYCOPERDON. In Ruſſia we are told that they are eaten almoſt indiſcriminately, ſalted and thus kept for winter uſe. That many have ſuffered diſeaſe, and ſome even death from eating voraciouſly or incautiouſly of Funguſſes is certain; it is doubtful however whether many of them be really poiſonous, in the ſtrict and proper ſenſe of the word [c]. A great variety of inſects feed on the different ſpecies, particularly the *larvæ* or maggots, of many of the *Muſcæ* or Fly genus [d]. Some Funguſſes have been found of conſiderable uſe in ſtopping external hæmorrhages; and the acrimonious qualities of the others will probably at ſome future period be turned to good account [e].

For farther particulars of this tribe, ſee *Agaricus, Boletus, Clathrus, Clavaria, Helvella, Hydnum, Lycoperdon, Mucor, Oſtiſpora, Peziza, Phallus, Sphæria.*

FUSANUS. (*From* Fuſain, *which is the French name for Euonymus or Spindle-tree.*)

Claſſ. 23. 1. Polygamia Monoecia.

Nat. order of *Elæagni*, Juſſieu 75.

GENERIC CHARACTER.

* *Hermaphrodite.*

CAL. *Perianth* one-leafed, turbinate, half-five-cleft four-cleft, *Berg*): *clefts* ovate-acute, from flat ſpreading, with the tips globoſe-uncinate, ſomewhat concave.

COR. none.

STAM. *Filaments* four, linear, grooved in the middle, a little longer than the germ, inſerted into the calyx near it, and occupying the ſinus of it. *Anthers* roundiſh, compreſſed, four-lobed, erect.

PIST. *Germ* large, turbinate, almoſt inferior, wide at top, from flat ſomewhat concave, ſtriated, quadrangular, with four hollowed ſinuſes, each on each ſide of the germ ſolitary. *Style* thick, very ſhort, ſubquadrangular. *Stigmas* four, obtuſe, cruciform, ſmall.

PER. Drupe.

* *Male.*

CAL. *&c.* as in the hermaphrodite, but the fruit abortive.

ESSENTIAL CHARACTER.

HERM. *Cal.* five-cleft. *Cor.* none. *Stam.* four. *Germ.* inferior. *Stigmas* four. *Drupe.*

MALE. *Cal.* &c. of the former. *Fruit* abortive.

[a] Hort. kew.

[b] Withe. arr. 3. 31. to 34. Philoſ. tranſ. 51. 138. Gentl. mag. for 1775. p. 316. Hedwig.

[c] Withering. [d] Curtis. [e] Withering.

blunt indentures along the edge, bright green, and slightly villose; the upper ones are almost entire. Peduncles simple, naked, long, terminating, bearing one handsome flower, purple and yellow, two inches in diameter. Scales of the calyx ciliate or hispid at the base, the inner ones smallest. Hermaphrodite florets hispid on the outside. Receptacle slightly convex. Seeds turbinate, crowned with from five to eight sharp, scarious chaffs which form the egret.

This fine plant has been cultivated a few years in the royal garden at Paris[†].

M. Fougeroux informs us that M. le compte d'Essuiles brought the seeds from Louisiana, and that the plants had produced seeds in the Paris garden in 1784 or thereabouts. It is an annual, and flowers in july and august, and continues to the end of october.

GALARIPS. See *Allamanda.*

GALAX. (Γαλαξ, *Milk: which was probably the original noun, since it forms* γαλακτος *in the genitive.*)
Lin. gen. n. 276. *Reich.* 296. *Schreb.* 382. *Juss.* 420. Viticella. *Mitch.* 24.
Class. 5. 1. Pentandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* ten-leaved: outer leaflets alternate, shorter, lanceolate, reflex; inner longer, lanceolate, acute, upright.
COR. one-petalled, salver-shaped: *tube* cylindric, length of the calyx; *border* flat, five-cleft, segments obtuse.
STAM. *Filaments* short. *Anthers* roundish converging within the throat of the corolla.
PIST. *Germ* ovate, villose. *Style* filiform, semibifid, length of the stamens. *Stigmas* roundish.
PER. *Capsule* ovate, one-celled, two-valved, coloured, elastic.
SEEDS two, large, convex, ovate, callous, as it were single two-lobed.

ESSENTIAL CHARACTER.

Cal. ten-leaved. *Cor.* salver-shaped. *Capf.* one-celled, two-valved, elastic.

SPECIES.

1. Galax aphylla.
Lin. spec. 289. *Reich.* 1. 562. *Gron. virg.* 34. Viticella. *Mitch. gen.* 24.
Anonymos f. Belvedere. *Clayt. n.* 4. *Gron. virg.* 25.

DESCRIPTION, *&c.*

This plant is a native of Virginia, as yet very rare and little known in Europe. Leaves all radical. Stem naked, simple, probably woody. Flowers in a loose, terminating spike[‡].

GALAXIA. (Γαλαξιας κυκλος, *is the milky way; thus* γαλαξιας φυτον, *is a milky plant.*)
Lin. gen. Schreb. n. 1103. *Thunb. nov. gen.* 50. *Cavan. diss.* 6. 340. *t.* 189. *Juss.* 57.
Class. 16. 1. Monadelphia Triandria.
Nat. order of *Ensatæ*, *Irides*, Juss.

GENERIC CHARACTER.

CAL. *Spathe* one-valved, membranaceous, converging.
COR. one-petalled, superior. *Tube* filiform, long, erect, a little widened at top. *Border* six-parted: *parts* obovate, obtuse, spreading; the three outer ones having a nectareous pit.
STAM. *Filaments* three, united in a cylinder. *Anthers* ovate.
PIST. *Germ* inferior, obtusely triangular, smooth. *Style* filiform, a little longer than the stamens. *Stigmas* three, filiform-many-parted, spreading.
PER. *Capsule* oblong-subcylindric, three-grooved, three celled, three-valved.
SEEDS very many, globular, very small.

ESSENTIAL CHARACTER.

Spathe one-valved. *Cor.* one-petalled, six-cleft; tube capillary. *Stigma* many-parted.

SPECIES.

Ixia fugaciffima. *Lin. suppl.* 94.
Leaves linear-filiform.

DESCRIPTIONS, *&c.*

1. Root filiform, fixed to an ovate netted comose bulb; there are usually several of these conglomerate. Stem none. Root-leaves heaped sheathing ovate obtuse slightly veined longitudinally flat smooth, the edge somewhat cartilaginous. The calyx is a very thin sheath. The corolla is variegated with yellow purple and violet. The capsule is smooth. It flowers from june to september.

2. Root as in the preceding. Leaves radical, in bundles, broader at the base, then linear, bristle-shaped at the tip, entire, channelled, smooth, very nearly an inch in length. Flowers radical, among the sheathing leaves, in bundles, sessile, with a long capillary tube, the length of the leaves. Corolla yellow, varying with a yellow tube and a violet-coloured border.

These are both natives of the Cape of Good Hope, where they were found by Thunberg[†].

GALAXIA *obscura.* See *Morœa vegetellanica.*
GALBANUM. See *Bubon.*

Class. 17. 4. Diadelphia Decandria.
Nat. order of *Papilionaceæ* or *Leguminosæ.*

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular, short, half-five-cleft: teeth subulate, nearly equal.
COR. Papilionaceous: *banner* large, ovate, reflex at the end and on the sides; *wings* oblong, having an appendage, and being almost the length of the banner; *keel* oblong, compressed, straight, towards the end gibbous below, sharp above.
STAM. *Filaments* diadelphous (simple and nine-cleft). *Anthers* oblong.
PIST. *Germ* slender, oblong. *Style* slender, shorter than the germ, ascending. *Stigma* a very small dot at the end.
PER. *Legume* very long, compressed, acuminate, scored with oblong streaks between the seeds.
SEEDS several, oblong-kidney-shaped.

ESSENTIAL CHARACTER.

Cal. with subulate teeth, nearly equal. *Legume* with oblique streaks, between the seeds.

Spikes terminating peduncled, legumes cylindric pedicelled spreading, stem and leaflets hoary-tomentose.

DESCRIPTIONS, *&c.*

1. Root perennial, composed of many strong fibres, which are frequently jointed. Stems channelled, hollow, from two to three, or even five feet in height. Leaves unequally pinnate, composed of five or seven (Haller says nine or ten) pairs of smooth, entire leaflets. Flowers terminating, in loose spikes; they are of a pale blue colour, appear in june, and are succeeded by taper pods, about an inch and half in length, and ripening towards the end of auguſt.

There is a variety with white, and another with variegated flowers.

β. The African plant has larger leaves, composed of eight or ten pairs of leaflets, broader and blunter; the flowers are larger, the spikes longer, and the seed-pods much thicker.

Goat's-Rue is accounted cordial, sudorific and alexipharmic. Mr. Boyle celebrates its virtues in pestilential and malignant diseases.

Native of Spain, Italy, Hungary, and Africa. Cultivated by Gerarde in 1596[a]. He names it *Italian Fitch* and *Goat's-Rue*.

By some mistake, this plant is set down by Parkinson, as having been found wild near Linton in Cambridgeshire, where it was certainly never seen growing wild by any person.

2. This is a small herbaceous plant, somewhat of an ash colour, seldom growing above eleven or twelve inches in height. It is common among the bushes in all the Savannas about Kingston in Jamaica[b].

3. Stems round, branched, villose, procumbent unless it be supported by neighbouring shrubs. Tendrils none. Stipules lanceolate-acuminate, villose, quite entire. Leaves unequally pinnate; the midrib villose, grooved, two or three inches long; leaflets about six pairs, oblong, attenuated at the base, blunt, quite entire. Racemes simple, stiff, subterminating with a peduncled flower or two frequently in the axil of the leaf. Flowers flesh-coloured, inodorous. Legumes villose, sharp, brown, an inch and half long. Seeds variegated.

Native of Carthagena in America, on sandy shores[c]: and every where between the Tropics[d].]

4. Root perennial. Stem annual, three feet high. Leaflets generally seven or nine. The whole plant is covered with a silvery down. Flowers red, in spikes at the ends of the branches. Legumes silvery.

[Stem erect in its place of native growth, which is in North America. Flowers three or four[e].

5. Plant procumbent. Stem round. Leaflets (thirteen to seventeen) blunt with a point, streaked at an acute angle, the lower ones shorter and obovate. Spike terminating, peduncled. Calyxes gray with hairs. Stipules bristle-shaped[f].

Native of the East Indies.

6. Stems or branches white with down. Stipules in pairs, spreading. Peduncles axillary, solitary, short, one-flowered. Flowers upright, small. Legume hanging down.

Found in Coromandel by König[g].

7. This is the largest of the genus. Stem angular, smooth, changing direction variously between the joints. Leaflets between oval and lanceolate, blunt with a point, subpetioled, beautifully streaked at an acute angle underneath. Racemes terminating, very long; with ovate, acuminate, alternate, bractes; within each are three filiform peduncles supporting as many flowers, with banners broader than the leaves. Calyxes smooth. Legumes like those of the Vetch.

Native of Ceylon[h].

[a] Hort. kew. [b] Browne. [c] Jacquin. [d] Forster. [e] Linn. [f] Linn. zeyl. [g] Linn. suppl. [h] Linn. zeyl.

8. Stem ſhrubby, round, branched, having very minute hairs ſcattered over it. Leaves unequally pinnate: leaflets in ſix pairs, on ſhort petioles, the outmoſt larger, outwardly a little wider, awned, the upper ſurface ſmooth, the lower appearing hairy when magnified. Petiole ſcarcely pubeſcent. Stipules ovate, nerved, purpliſh. Peduncles terminating, erect, elongated: flowers at the top, oppoſite, approximating, nodding. Bracteas ovate-oblong, acute, purpliſh, deciduous. Calyx tomentoſe-ſilky. Corolla purple: banner ſmooth above. Legume compreſſed, cloſely ciliate about the edge.—*G. virginiana* differs from this in the ſtem being villoſe, the leaves having ten or twelve pairs of leaflets, not wider outwards, the bractes awl-ſhaped, and the legumes every where villoſe[1].

Native of the Cape of Good Hope, whence it was introduced by Mr. Francis Maſſon in 1774[2].

9. Native of the Cape of Good Hope. Introduced by Mr. Fr. Maſſon in 1787. It flowers in july[3].

10. Native of India and the South Sea iſlands. Introduced in 1778, by Patrick Ruſſell, M. D. It flowers in june and july[4].

11. Perennial. Stem leſs angular and ſtraighter than the ſeventh, reddiſh. Leaflets (thirteen to ſeventeen) blunt with a point, ſtreaked at an acute angle. Flowers narrower than the leaves. Bracteas ovate; within each two flowers with capillary peduncles. Legumes like thoſe of the Vetch, aſcending at the tip, compreſſed, a little toroſe[5].]

Mr. Miller ſays, this plant was annual here; that it had an herbaceous ſtalk, two feet high; that the leaves had eight or nine pairs of leaflets; that the peduncles came out oppoſite to theſe; and that the flowers were ſmall, purple, in a looſe ſpike, and ſucceeded by ſlender erect pods. He received the ſeeds from Ceylon and many other parts of the Eaſt Indies.

[It was cultivated in 1768, by him; and flowers in july and auguſt[6].

12. This is an upright, branched ſlender ſhrub, two feet high. Stipules briſtle-ſhaped, entire. Leaves unequally pinnate, three inches long, often diſtich: leaflets about ten pairs, oval-oblong, blunt with a briſtle-ſhaped point, quite entire, ſmooth on both ſides. Racemes axillary, looſe, ſimple, ſtiffly ſpreading, ſolitary, longer than the leaves, ſix-flowered or thereabouts. Flowers inodorous, red and white variegated. The two upper ſegments of the calyx leſs deeply cut, and ſhorter than the others, and the loweſt ſegment longer than any. Banner obtuſe, emarginate, ſpreading very much, on a ſhort claw; keel roundiſh-ſickled, acuminate. Style ſlightly hirſute, riſing almoſt at a right angle. Legume linear, flat, blunt with a point, tranſverſely grooved between the ſeeds, brown, ſmooth, pendulous, or even bent back to the raceme by the incurved peduncle. Seeds black, ſhining.

Native of the Caribbee iſlands[7].

13. Branches ferruginous, tubercled with black dots, on the top of the ſtem tomentoſe. Leaflets blunt. Stipules awl-ſhaped. Racemes upright, reſembling thoſe of Aſtragalus Alopecuroides; flowers numerous, heaped, blue.—Found in South America by Mutis[8].

14. A very handſome plant. Stems naked, flexuoſe, ſmooth, angular. Leaflets eleven, oblong, blunt, ſmooth above, ſilky underneath, hairy, ſtreaked, the lower ones ſhorter. Peduncles from each axil, naked, ſpiked at the end, the length of the leaves, ſmooth. Calyxes ſubvilloſe. Legumes like thoſe of Lathyrus.—It is from this plant that the inhabitants of Ceylon prepare their Indigo, which yields a dye of a pale blue colour[9].

15. This is a woody ſhrub, with a roundiſh ſtem, and a brown bark. Leaflets uſually nine, obovate, ſtreaked. Legumes like thoſe of Orobus.

Native of Ceylon[1].

16. Root annual or biennial. Stem reddiſh brown, ſomewhat villoſe, at a ſmall diſtance from the root producing branches which ſubdivide into others: branchlets ſtreaked, ſomewhat angular, villoſe, and ſometimes ſo copious, that they ſeem to weigh down the whole plant. Leaflets about five pairs, equal, oblong-lanceolate, on both ſides, eſpecially underneath, cloſely pubeſcent; uſually acuminate, but ſome of them obtuſe, and even ſlightly emarginate. The common petiole is grooved: the partial ones are very ſhort, round, ſomewhat villoſe, yellowiſh green. Stipules ſlender, villoſe, ſtraight, acuminate. Peduncles from the upper axils, uſually two together, ſeldom three, villoſe, reddiſh, ſhorter than the calyx; which is ſublabiate, villoſe, permanent, tinged with yellow. Corolla purple; banner rounded, emarginate, with an ovate, white ſpot at the baſe, and ſtreaked with white lines; villoſe at the back, eſpecially near the baſe; claw very ſhort, greeniſh yellow: wings oval, twice as long as the calyx, with ſhort claws, and forming almoſt a right angle with the banner: keel ſubovate, acuminate, two-valved, the valves cohering above the middle. Germ hoary; ſtyle cylindric; ſtigma almoſt globular. Legume pedicelled, at firſt ſlightly ſickle-ſhaped, but afterwards ſtraight, almoſt cylindric, villoſe, an inch in length. Seeds ovate brown. It differs from *G. ſinuoſa* in having the leaflets villoſe on both ſides, and not all emarginate; the flowers not in ſpikes, and the legumes by no means pendulous. Nor can it be referred to *G. ſenticoſa*, as appears from the deſcription in *Flora zeylanica*.—It flowered at Pavia the 31ſt of july 1783, and the ſeeds ripened on the 5th of ſeptember[2].

Native of the Cape of Good Hope, whence it was introduced here in 1787[3].

Vahl ſays, it differs from G. grandiflora in having the branchlets angular and villoſe, the leaflets villoſe underneath, the ſtipules awl-ſhaped, ſmall, villoſe, the bractes awl-ſhaped.]

17. Mr. Miller has not deſcribed it. He informs us that it was diſcovered by Dr. Houſtoun at Campeachy, whence he ſent the ſeeds to Europe.

[18. Stem villoſe-tomentoſe, angular. Leaflets from four to ſix pairs, an inch long, linear, obtuſe, mucronate, acute at the baſe, ſmooth above. Peduncles oppoſite to the leaf, a long ſpan in length. Flowers remote, on villoſe pedicels. Bractes in pairs, awl-ſhaped, ſhorter than the pedicel. Calyx villoſe. Banner villoſe, cinereous on the outſide. Legumes two inches long.—It differs from G. cinerea only in having narrower ſtipules, and the legumes in threes at each tooth of the peduncle[4].

19. This is a ſpreading ſhrubby plant, riſing generally to the height of five or ſix feet. The leaves and branches, well pounded, and thrown into a river or pond, very ſoon affects the water, and intoxicates the fiſh, ſo as to make them float on the ſurface, as if dead: moſt of the large ones recover after a ſhort time, but the greateſt part of the ſmall fry periſh on theſe occaſions.

It is a native of South America, whence it has been introduced to Jamaica, and cultivated there, on account of its intoxicating qualities[5].

PROPAGATION AND CULTURE.

1. This is propagated by ſeeds, ſown either in ſpring or autumn in an open ſituation. When the plants come up, keep them clean from weeds till they are ſtrong enough to remove; then take them carefully up, and plant them in a ſpot well dug and cleared, in rows a foot and half diſtant, and one foot aſunder in the rows; watering them till they have taken new root. Hoe the ground frequently between the plants; and dig it in the ſpring between the rows. If the ſtalks are cut down every year, before the ſeeds are formed, the roots will continue the longer, eſpecially on a light dry ſoil.—Or if the ſeeds be permitted to ſcatter, the plants will come up without any care.

4. This

4. This plant, although it is tolerably hardy, yet it is with difficulty preſerved in gardens; for the ſeeds rarely ripen in England, and the plants are often deſtroyed by froſts in winter. The only method in which I have been able to keep the plants, has been by potting them, and placing them in a common frame in winter, where they enjoyed the free air in mild weather, but were protected from froſt; in this way I have kept it three years, but it has not ripened ſeeds here.

The other ſorts from the Eaſt and Weſt Indies may be propagated by ſeeds ſown on a hot-bed in the ſpring. When the plants are ſtrong enough, tranſplant each of them into a ſeparate ſmall pot, and plunge them into a hot-bed of tanner's bark, ſhading them till they have taken new root. Then treat them as other tender plants, preſerving them through the winter in the bark-ſtove. They will flower in July, and perfect their ſeeds in September.

If the plants are brought forward early in the ſpring, and the ſummer proves warm, the ſeeds may ripen here.

Lin. ſyſt. 375. *ſuppl.* 227.

Procumbent; leaves ovate channelled, patulous and recurved at the tip.]

DESCRIPTIONS, *&c.*

Stem four or five feet high, ſending out many weak branches. Leaves very narrow, placed irregularly on every ſide, of a light green, with a furrow running longitudinally through the middle. Flowers in looſe panicles from the ſides and at the ends of the branches, very ſmall, and making little appearance.

[It is a ruſtic ſhrub, with the air of *Tetragonia*, but all the parts minute, and the whole of it obſcurely papilloſe or bladdery. Stem round, with a few reflex little briſtles. Leaves oppoſite, ſeſſile, perennial. Flowers ſeſſile, white, in a dichotomous panicle [a].

Native of the Cape of Good Hope. Cultivated in 1752, by Mr. Miller. Flowering from june to auguſt [b].

2. Found at the Cape of Good Hope, by Thunberg [c].]

PROPAGATION AND CULTURE.

Theſe plants will not live through the winter in the open air in England, but muſt be placed in the green-houſe, or under a frame, with other hardy exotic plants, where they may have a large ſhare of air in mild weather, for they only require to be protected from froſt. In the ſummer they may be expoſed in the open air, with other plants of the ſame country, and in dry weather they muſt be frequently watered. They may be propagated by cuttings, which if planted during any of the ſummer months and watered frequently, will take root in five or ſix weeks, and may then be treated as is directed for the old plants.

Six flowers in a whorl; involucre of four leaves: (flowers ſix to twelve, with an involucre of as many leaves as flowers).

DESCRIPTIONS, *&c.*

[Stem herbaceous four-cornered. Leaves oppoſite. Flowers in whorls.

1. Root annual. Stem upright, a foot high, purpliſh, ſomewhat hairy or nearly ſmooth, brachiate, the knots ſcarcely ſwoln. Leaves petioled, entire or ſlightly and diſtantly toothed, acuminate, naked or a little hairy, of a pale green colour. About eighteen flowers in a whorl. Calyx hairy, teeth a little unequal, hardly to be called thorny or pungent, they are acuminate, and terminate in awns as long as the teeth. Corolla reddiſh purple, and ſomewhat villoſe; upper lip toothed; lower lip bent back, irregularly notched, with two oval yellow ſpots within, but underneath and on the outſide many ſmall white globules. Frequent in corn-fields, in a calcareous ſoil, flowering from june to auguſt [a].

Monſ. Villars has a ſpecies, which he calls *intermedia*, becauſe it ſeems to be a connecting link between this and G. Tetrahit. The calyx has no awns like this, but the flowers are only half the ſize of thoſe of Tetrahit, which are ſmaller than thoſe of Ladanum. The whole plant is viſcid. It is not Ladanum ſegetum of Rivinus, but it approaches to it a little. The ſtem is from eight to ten inches high; the branches leſs frequent than in Ladanum; the leaves oval, blunt, villoſe and toothed; the flowers red, ſeldom white, extending little beyond the calyx.

2. Root annual branched. Stem thicker, higher, and more branched than the foregoing, purpliſh, obſcurely quadrangular, grooved and villoſe. Leaves much broader, the ſerratures more in number and more regular, thoſe next the root ovate, thoſe on the ſtem lanceolate, acuminate, villoſe or ſilky, with ſtraight veins. Whorls more and nearer to each other. Calyx more hairy, the teeth ending in ſtiff awns. Corolla pale yellow and villoſe, of a deeper yellow about the throat: upper lip toothed, often variegated with pale purple, lower notched or ſcolloped, ſometimes alſo variegated with purple. This has very much the air of the foregoing, of which Linneus makes it only a variety; it differs however in the breadth, ſerratures, veins, and hairineſs of the leaves, as well as in the colour of the flowers [b].

Native of Germany, Switzerland, and England, as in ſandy corn fields of Cambridgeſhire, Nottinghamſhire, Yorkſhire and Lancaſhire, and about Bangor in Wales; flowering in july and auguſt.

3. Root annual. Stem upright, covered with ſtiff hairs, ſwoln under the joints. Leaves ovate-acuminate, ſerrate, hairy and rough eſpecially on the upper ſurface, two inches or more in length, and near half an inch in breadth; the petioles hairy, grooved above, and near an inch long. Flowers ſeſſile, ſeventeen or eighteen in a whorl; each whorl ſupported by a pair of leaves, and ſubulate, thorny bractes. Calyx ſtreaked, villoſe, the teeth terminated by ſharp awns, as long again as thoſe of *G. Ladanum*. Corolla twice as long as the calyx, either purple or white, with a ſpot on the lower lip variegated with purple and yellow; upper lip notched or ſcollopped, villoſe on the outſide; ſegments of the lower emarginate and ſmooth: nectaries ovate, obtuſe, at the baſe of the germ: anthers greeniſh, ſingularly two-lobed and hairy; ſtyle white; ſtigma red; both ſmooth. The ſwoln part of the ſtem, and the teeth of the calyx are covered with ſmall glands [c].

Every part of the plant is rough with very ſharp prickles, and has a ſtrong ſmell when bruiſed.

In corn fields, and on the borders of them, on waſte grounds, in coppice woods, &c. flowering in july and auguſt. In Yorkſhire they call it *Dog Nettle*, which I ſuppoſe is a corruption of Dead Nettle, and confounds it with Lamium.

β. The flower of this variety is large and elegant, above double the ſize of the foregoing, the corolla four times as long as the calyx, ſtraw-coloured, and the lower lip ſpotted with purple. Haller, Miller, Curtis, Smith, Pollich, and Krocker, make it a ſeparate ſpecies; but the ſtructure of the whole plant being the ſame, Linneus will not allow it to be any thing more than a variety. All the parts are much larger and ſofter [d].

In Germany, Switzerland, Sweden, &c. In Great Britain, in the northern counties, as about Keighley, Settle, &c. Gretna Green, Moffat, and near Edinburgh. Alſo in Eſſex, at the bottom of Ribton lane, near Woodford. Norfolk, near Norwich.

γ. Corolla white ſlightly tinged with red, and the lip marked with yellow, riſing from a purple calyx. Joints of the ſtem red. Leaves narrower, of a deeper green, and the whole air different from the common ſort. Mr. Doody obſerved this many years near the Neat-houſes, and in the way from thence to Chelſea.

δ. Corolla white and very large.—Obſerved by Merret along the ditches from Scrooby to Sherwood foreſt, and by Mr. Lawſon on the ſkirts of Croſs-Fell and other places of Weſtmoreland and Cumberland [e].

Monſ. Villars has a new ſpecies, under the name of *G. proſtrata*. He refers to Merret, but ſays that the flowers are yellow. Its low, ſimple, villoſe ſtem, and its large flowers, make it a diſtinct ſpecies, in the opinion of Mons. Villars; but it ſeems much diſpoſed to vary.

Dr. Smith obſerved a remarkable variety at Matlock in 1788, with the terminating flowers always regularly four-cleft and ſalver-ſhaped, with four equal ſtamens, whilſt all the reſt had their proper form.

4. With reſpect to this ſpecies there has been a great diverſity of opinion. Haller makes it a *Car-*

[a] Linn. Huds. With. Woodw. Mſs.

[b] Krocker and Hudſon. [c] Pollich, Lightf. Wither. Woodw. Mſs.
[d] Linn. ſuec. Pollich. Woodw. Mſs. [e] Ray ſyn.

diaca.

diæca, Scopoli, a *Leonurus*, and Crantz a *Lamium* Mr. Hudſon has created a new genus for it under the name of *Galeobdolon*, in which he has been followed by Mr. Curtis and Mr. Relhen; Dr. Withering and Dr. Smith. I am averſe from dividing the genera of plants, as I find them conſtituted by Linneus, without great neceſſity, and therefore leave this in the genus *Galeopſis*. Root perennial. Stems ſeveral, ſomewhat hirſute, furrowed, thoſe producing flowers are nearly upright, from a foot to two feet in height, the barren ſtems, after flowering time is paſt, extend to a great length, and creep. Leaves petioled, ſlightly hirſute, eſpecially at the edges, unevenly ſerrate, and veiny; the lower ones heart-ſhaped, the upper ones ovate, pointed and ſeſſile. The whorls have from ſix to twelve ſeſſile flowers, protected by an involucre, of as many briſtle-ſhaped leaves as there are flowers. Calyx ſlightly hirſute, marked with ten raiſed lines, alternately ſtronger and fainter; the teeth nearly equal and acuminate; the uppermoſt upright, and at a diſtance from the reſt, the two lowermoſt ſpreading open, and ſomewhat turned back. Corolla yellow, with the middle ſegment of the lower lip tawny, marked with three lines; the whole lower lip beautifully ſpotted with tawny or deep orange; tube a little longer than the calyx, purple and hairy within: upper lip upright, long, villoſe, edged with villoſe hairs, entire or nearly ſo; lower lip ſhorter, the lateral ſegments ovate, acuminate, with the outer ſide bent back; the middle one longer, ſtraight and acuminate. Filaments yellow: anthers two-lobed and purpliſh, fleſhy or glandular on the back part: pollen whitiſh. Style purple. Seeds browniſh-black, ſomewhat ſhining, oblong, convex on the outer ſide, three-cornered on the inner.

Native of Sweden, Germany, Switzerland, Auſtria, Carniola, Italy, Britain, &c. In ſome parts of the iſland frequent, as in Charlton, Hampſtead, and ſome other woods near London; in Kent, Eſſex, Cambridgeſhire, Suffolk, Norfolk, Worceſterſhire, Staffordſhire, Warwickſhire.

It flowers in may and june.

It is found with variegated leaves[1].]

PROPAGATION AND CULTURE.

All the ſpecies, except the laſt, being annual, muſt be propagated from ſeeds, but being common weeds are ſeldom cultivated in gardens; [though the firſt variety of the third ſpecies makes no bad appearance, and was therefore not unaptly named *ſpecioſa* by Mr. Miller. As weeds among corn they are not very injurious, nor difficult of extirpation.

The fourth ſort is perennial, and may be propagated plentifully by the runners, which it throws out too abundantly. When the foliage is variegated, it makes a beautiful appearance in a garden. This being a wood plant, ſhould not be too much expoſed to the ſun.

Leaves in fours ovate hairy, ſtem ſimple above, hairy, bunches of flowers lateral with two leaves, flowers polygamous, fruit ſmooth.

DESCRIPTIONS, *&c.*

Root uſually dying red, in moſt of the ſorts perennial. Stems herbaceous, four-cornered. Leaves ſeſſile, in whorls or ſurrounding the ſtem in form of a ſtar. Flowers either terminating in a kind of panicle, or elſe axillary. Fruit ſmooth, wrinkled or ſet with hooked ſtiff hairs or prickles.

1. This has the appearance of *G. boreale*, but the leaves are double the breadth, with the nerves three in number, and ſcabrous underneath. The ſtem firm and upright. The panicle of flowers ſhort and conglomerate. The ſeeds ſmooth and even[a]. Stems a foot high and more, ſlender, ſwelling at the joints, purpliſh brown, rough when rubbed from the bottom upwards. Leaves reflex on the edge, but not at the end. Corolla white. Seeds very ſmooth and gloſſy[b].

Native of the Palatinate, Sileſia, Idria, &c. flowering in july.

Perennial. Introduced in 1775, by Drs. Pitcairn and Fothergill[c].

2. Root ſlender, creeping, perennial. Stem flaccid, branched from the joints, a foot or more in length, the corners ſet with ſharp hooked prickles, pointing downwards. Leaves in fours on the branches, on the ſtem ſometimes five or even ſix, under the flowers in pairs, thoſe at the baſe of the branches largeſt, of different ſizes in the ſame whorl lanceolate, obovate, or ovate-lanceolate, very obtuſe, ſmooth except at the keel and edges, which are ſet with very ſhort hooked hairs. Flowers numerous, white, on lateral and terminating peduncles, which are uſually trifid, and ſubdivided[d].

Common on the banks of rivers and ditches, and in moiſt meadows; flowering in july.

Dr. Withering has obſerved a dwarf variety, ſimilar to the foregoing, but ſcarcely a foot in length; reſembling the figure of *G. triflidum* in the *flora danica*, but readily diſtinguiſhable by the corolla of four diviſions, and the divided peduncles.

Dr. Withering has alſo obſerved another variety, reſembling the *paluſtre*, except that the leaves grow in ſixes. Dr. Stokes remarks, that the leaves are narrower, but always blunt and generally unequal; that it is as large as the *paluſtre*; that the branches are next in roughneſs to thoſe of *G. Aparine*, *ſpurium*,

[a] Linn. ſpec. [b] Scopoli, Pollich, Krocker. [c] Hort. kew. [d] Withering, Stokes in With. Pollich, Leers, Krocker.

and *Valantia Aparine*; that he has been accuſtomed to refer it to the *uliginoſum*; but that the inequality and bluntneſs of the leaves, and the want of the thorn-like point at the end of them, induces him to believe it, with Haller and Ray, to be a variety of the *paluſtre*; though, being found in the ſame ſituations, it is not unlikely but it may turn out to be a diſtinct ſpecies.

3. Root annual, very ſmall and ſlender. Stem ſlender, bent back, ſtiffiſh, hairy, very much branched from the bottom almoſt to the top, the branches three or four together, divaricate. Leaves broadiſh, obtuſe, ſmooth, only a little ſcabrous underneath. Peduncles uſually in threes, very ſlender, the length of the leaves, one-flowered; the flowers very ſmall, white and three-parted. Stamens three. Fruit very ſmall, ſmooth and even.—Native of Denmark, Sileſia, Canada[a]. It flowers in july.

4. Stature between *G. Mollugo* and *glaucum*. Stem weak, rough. Leaves in fives on the ſtem, reflex ſubulinear; on the branches in fours. Flowers in trifid corymbs, white, purpliſh on the outſide before they expand. Anthers brown[b].—According to Haller the leaves are in eights. Pollich makes them eight on the ſtem, and ſix on the branches. Krocker, five to eight on the ſtem, and four to ſix on the branches. Haller deſcribes the ſtem to be three feet high, round, firm, upright, ſwelling under the leaves, not much branched. Leaves narrow, hollow and glaucous underneath, ending in a ſhort awn ſharper towards the top of the ſtem; ovate-lanceolate, and ſmaller under the flowers. Peduncles branched, many-flowered, ending in a kind of convex umbel. The flower is among the largeſt of this genus, and white. The peduncle ſwells under the ſeeds.

Pollich adds, that the ſtem is very ſmooth, glaucous-green, and ſays that it is divided into many branches: that the leaves are hardiſh, a little rolled back on the edge, ſmooth and glaucous above, ſcabrous, whitiſh, and grooved beneath.

The root, according to Krocker, is redditſh. The ſtem eighteen inches high, ſcabrous, branched, very ſmooth, glaucous, upright, obſcurely four-cornered.

Theſe deſcriptions do not perfectly agree; and after all, Gouan (illuſtr. p. 6) is of opinion that this and the *glaucum* are but one ſpecies.

Native of Germany and Switzerland.

5. Diſtinguiſhable from G. paluſtre (ſays Ray) by its ſmalleneſs, ſmoothneſs of its ſtems and leaves, and place of growth, namely on hills.—Perennial. Stems and branches matted together, and ſpreading on the ground. Flowering-ſtem from two to ſix inches high, twiſted, appearing cylindrical to the naked eye, but when magnified to have four rounded corners. Leaves often in fours at the bottom of the ſtem, five about the middle, and ſix at the top, unequal in ſize in the ſame whorl, ſometimes obovate-lanceolate, the edges beſet with minute prickly hairs pointing towards the end, the keel ſmooth: thoſe of the branches ſometimes in fives. Peduncles lateral and terminating, ſingle, biſid or trifid, ſpringing from the whorls at the joints of the ſtem.—Lightfoot takes this to be only a variety of *uliginoſum*, growing in dry and mountainous paſtures: but Dr. Stokes has found it to be the ſame in marſhes as on hills. Heaths and mountains, alſo in marſhy places. In Dudley Wood. It flowers from june to auguſt[c].

6. Perennial. Stem very much branched next the root. Flowering ſtems upright, ſimple, ſharply quadrangular, herbaceous, green. The whole plant ſhining. Leaves in ſixes, then fives or fours, half round, ſubulate, ſomewhat ſcabrous about the edge, but hardly to be known by the touch, bowed upwards. Flowers in a terminating panicle; corolla white, larger than the fruit, which is oblong ovate, bowed in, black and wrinkled.—Native of the county of Nice, &c. in dry places: alſo probably in Dauphiné[d].

7. This abounds in the woods of Canada; the roots are employed by the Indians in dying the quills of the American porcupines red. The French women there ſometimes dye their clothes with theſe roots, which are but ſmall, like thoſe of *G. luteum*. Neither air, ſun, nor water change the colour[e].

8. Root perennial, creeping, ſlender. Stems from procumbent erect, often putting out roots at the baſe, from a finger's length to a foot or eighteen inches, the corners rough, with very minute prickles; two or more branches ſpringing from each joint. Leaves ſix, ſometimes ſeven or eight, or even nine in a whorl; five lines long, and one broad, lanceolate, not much bent back at the edge, which is ſet with very minute prickles; in other parts they are ſmooth, of a bright green above, but glaucous underneath. Flowers in panicles at the ends of the ſtem and branches, in trifid diviſions, the peduncles very ſhort: at the baſe of theſe a pair of leaflets or bractes. Corolla white, larger than the fruit; Haller ſays it has a tinge of roſe colour. Anthers very ſmall, purpliſh[f]. Fruits rough, according to Tournefort[g].

Native of Sweden, France, Germany, Switzerland, Great Britain; on wet heaths, in bogs, low meadows, by river ſides, and other watery places. It flowers in july and auguſt.

9. Stem quadrangular, proſtrate, hardly branched, prickly downwards at the corners. Leaves uſually in ſixes, ovate-lanceolate, prickly backwards, keeled. Peduncles axillary and terminating, bowed in, three-flowered, all the flowers hermaphrodite. Seeds globular, ſmoothiſh. Style biſid. Stigmas globular. Bractes ſubulate at the baſe of the pedicels[h].

Such certainly is our Cambridgeſhire plant, and it agrees with the ſpecific character given by Linnæus, as alſo with his obſervation, that it is allied to *G. Aparine*, but is ſmaller.—Haller aſſures us that the ſpecimen ſent him by Mr. Hudſon was *Valantia Aparine*; and Dr. Stokes informs us that his ſpecimens from the garden of Mr. Sole at Bath, who probably had his plants from Cambridgeſhire, were alſo *V. Aparine*; and yet none but hermaphrodite flowers have been obſerved by the late Mr. Lyons, Mr. Relhan, or myſelf.—There can be no doubt of our plant being *Aparine ſemine leviore* of Ray; who ſays that it is of a lower growth than *G. Aparine* or common Goofe-graſs, with the runners or bottom branches ſhorter; the leaves ſmaller, leſs hirſute and paler; the ſeeds not entirely ſmooth, but much leſs hirſute.—Haller's deſcription is very ſhort, but as he aſſerts that all the flowers are androgynous, ours can ſcarcely be the ſame plant with his n. 724. Nor is it his n. 725, though he makes *A. ſem. levi* of Vaillant, and *A. ſem. leviore* of Ray, ſynonymous with it; for that alſo has androgynous flowers. Gærtner has a ſpecies (p. 109) which he calls *Gallum biſpidum*, and which he makes ſynonymous with this of Haller: and they are both ſynonymous with *Valantia Aparine* of Linnæus. See n. 10. Nor can it be Krocker's *G. ſpurium*, to which he attributes pale yellow flowers. It agrees very well with the deſcription given by Leers.—Stems ſcarcely a foot high, diffuſed; joints equal, naked; leaves at bottom ſix, above four. Fruit ſmooth, at length becoming wrinkled and brown.—There is little doubt but that it is the ſecond Aparine of Parkinſon, though he deſcribes the leaves as not at all rough, or ſticking to what they touch. It is alſo the third *Aparine* of Morriſon.—Neither of theſe authors have figured it.

It is very common in the corn in Cambridgeſhire, eſpecially where the ſoil is calcareous, as about Gogmagog hills, Linton, &c. Alſo in various parts of Oxfordſhire.—According to Hudſon, in the iſle of Thanet; about Leatherhead, and elſe-

[g] Fl. paris.
[h] Lyons in Relh. cant.

where

where in Surrey; and near Stamford.—In the Iſle of Wight, as Dr. Withering ſays.

It is an annual plant, and flowers in june and july, and even later in the ſtubble after the corn is off. Smith refers this to the next ſpecies.

10. Leaves from ſix to eight, the upper ſurface ſmooth, the rib underneath rough. Umbels on peduncles, generally two to a whorl, oppoſite, dividing into three branches, not leafy at the baſe. The peduncles are prickly. bear three flowers, and are curved downwards. Fruit roughiſh, beſet with a number of minute tubercles, but which do not end in hairs.

This plant appears to be different from Aparine ſemine lævi ore of Ray, which is commonly taken for G. ſpurium of Linneus. It much reſembles G. Aparine, and is clearly of the ſame natural genus with the Galiums, although Linneus inſerts it among the Valantias.

11. Root annual, branched. Stems from a foot to eighteen inches in height, the corners rough with prickles pointing backwards, jointed, branched, branches alternate, flowering branches oppoſite. Leaves ſix or ſeven in a whorl, reflex, lanceolate or linear-lanceolate, naked. Panicle terminating; peduncles trifid. Corolla greeniſh yellow, ſmall. Seeds larger than the corolla, ſmooth[a].—The prickly hairs at the edge of the leaves point forwards; and ſometimes there are a few ſcattered hairs on the ſurface; thoſe of the branches are generally in twos, as in Ray's figure. Branches rough. Peduncles ſmooth, generally dividing into three, one of them ſupporting two flowers; ſometimes dividing ſimply into three or two[b]. Flower herbaceous, ſeed ſmall, roundiſh, leſs rough than in the other ſpecies of Aparine[c].

Dr. Stokes cannot diſcover any difference between *G. pariſienſe* of Linneus and *G. anglicum* of Hudſon, except in the roughneſs and ſmoothneſs of the fruit which induces him to believe that they are mere varieties.

Found by Sherard on a wall at Hackney, and at Eltham by Hudſon, in ſandy ground between Dartford and Northfleet, and on a wall at Farningham in Kent.—by Mr. Crowe, on the walls of Bunham church in Norfolk.

12. Scarcely a hand high. Root large, producing a prodigious number of ſtems, which are angular. Leaves in great abundance, without any prickle at the end. Peduncles one-flowered, very ſhort, ſcarcely emerging from the leaves, even when the ſeed is ripe. Seeds very large, wrinkled. This is Haller's deſcription, who doubts very much, whether his plant be the ſame with that of Linaeus.—Krocker ſays that it has a ſmall, ſlender, creeping root: a ſmooth ſtem, a hand or a foot in height; five or ſix leaves, oblanceolate or obovate, ſmooth, ending in a ſlender tip; the flowers axillary, the peduncles ſuſtaining one to four flowers, in a corymb, the corymbs four to ſix-flowered, ſhort. Corollas white. Seeds large. Perhaps this may be the *ſaxatile* of *Moench*, and the *barcynicum* of *Weigel*. It is an annual.

Native of Spain and Switzerland, on mountain rocks.

13. Stems weak, of a finger's length, and branched; the internodes ſcarcely the length of the leaves, which are ſmooth, ſomewhat convex, and mucronate. Native of the Pyrenees[e].

14. This very much reſembles *G. verum*, but it is leſs than a hand in height, and is decumbent. Stem quite ſmooth, not ſcabrous even about the edge. Leaves a little convex, not bent back on the edge. Fruit fleſhy, large, with the peduncles reflex, whence they are conglomerate.—Native of the Empire of Ruſſia. Perennial[f].

15. Root branched, perennial. Stems numerous, from three to ten inches high, branched, the corners commonly rough with prickles. They form large tufts covered with innumerable milk-white flowers, very conſpicuous at a diſtance. Leaves ſeven or eight, lanceolate or linear, ſcabrous, tipped with a ſhort pale briſtle; the lower ones imbricate. Seeds ſmall. It is allied to G. uliginoſum[g].—Not only the corners of the ſtem, but the edges and midribs of the leaves are rough, with ſhort ſpreading hairs. Leaves rarely up to eight[h]. In the Engliſh Botany it is ſaid from ſix to eight, or even nine in a whorl, equally ſpreading.

Native of Provence. On the limeſtone hills near Kendal in Weſtmoreland; flowering in auguſt.—Matlock Bath, Derbyſhire. July.

16. Root perennial, creeping, ſlender, ſomewhat woody of a yellow colour. Stem from one to two feet high, upright, ſlightly four-cornered, ſomewhat flexuoſe, ſcabrous, pubeſcent below ſlightly, above more obviouſly, pale green, branched towards the top; the joints cylindrical, ſubovate, whitiſh, ſurrounded with a ſlight margin: branches brachiate, oppoſite, alternately much ſhorter. Leaves about an inch in length, bluntiſh with a ſlight point, narrowed at the baſe, the edges rolled back, and rough with minute prickles turned upwards, viſible only with a magniſier, above ſlightly wrinkled, dark green and gloſſy, underneath hollowed and paler; the lowermoſt uſually eight in a whorl, but not unfrequently ten, the upper ones decreaſing to ſeven, and ſo down to two, and even one at the extremities of the branches. Flowers in a panicle, numerous, ſmall, fragrant with a peculiar odour. The panicle about a ſpan in length, interrupted, branched; the branches many-flowered, unequal, leafy, with ſingle leaflets on the pedicels. Corolla yellow[i]. It is obſerved by Dr. Withering, that the ſegments of the corolla are greatly expanded; that the ſtyle is cloven more than half way down; and that not only the corolla, but the ſtamens alſo and piſtil are yellow. It is common in moſt parts of Europe, in paſtures, and by the ſides of fields and roads, in a dry ſoil; flowering from june to auguſt and ſeptember. It will flouriſh in the moſt unremitting drought, when not a blade of graſs is to be ſeen.

Beſides the names ſet down in the title, Gerarde ſays it is called *Maids-hair*, and *petty Mugwet*, which laſt is from the French *petit Muguet*. I muſt obſerve that the common name *Bedſtraw*, (which we have from the German) is from the verb *to ſtrew* or *ſtrow*, anciently written ſtraw; thus the multitude *ſtrowed* branches in the way before Chriſt. Before the invention of feather-beds, a variety of herbs were uſed to ſtrew beds with; among theſe doubtleſs this was one: in Johnſon's edition of Gerarde, it is called *our Ladies Bedſtrow*. (p. 1127.) Strawberry is derived from the ſame origin.

It is an inveterate notion that the flowers and herb of this plant will curdle milk. Dioſcorides names it Γαλιον from this property. The ſame property is attributed to it by Galen. Matthiolus informs us that in Tuſcany they uſe it for this purpoſe, in order that their goat and ſheep's milk cheeſe may eat the ſweeter: Gerarde, who was a Cheſhire man, ſays, that in his country, eſpecially about Namptwich, they uſe it in their rennet, eſteeming that the beſt cheeſe which is made with it: and in ſome of the Weſtern iſles they curdle milk with a ſtrong decoction of this herb. Though no coagulation has followed in the experiments which I have ſeen tried, yet I ſhould not perhaps have ventured to diſpute the fact, were I not ſupported by Bergius and Krocker, who could not ſucceed in coagulating milk with this herb alone. The *Galium* has probably been put into milk deſtined to make cheeſe, not ſo much for the purpoſe of curdling it, as of giving it a flavour, or, as Matthiolus expreſſes it, to make it eat the ſweeter.

The French preſcribe the flowers in hyſteric and epileptic caſes[k]. Both theſe and the leaves diſcover a ſenſible acidity to the taſte; and the flowery tops committed to the ſtill as ſoon as gathered, give

[a] Hudſon. [b] Stokes in With. [c] Ray. [d] Linn. ſuppl. [e] Linn. ſpec. [f] Woodw. Mſ. [g] Withering. [h] Curtis.

over (says Lewis) a pretty ſtrong acid liquor in a moderate heat. The reſtringent and refrigerating virtues therefore aſcribed to this plant appear to have ſome foundation [y]. From this account I ſhould have been rather ſurpriſed that the trials to curdle milk have not ſucceeded with Bergius, Krocker and myſelf, had not the former aſſured us that he could not procure any acid in diſtillation.

Boiled in alum-water, the flowering ſtems dye of a good yellow colour. The roots dye a very fine red, not inferior to madder, but they are ſmall [z]. An ingenious gentleman, however, converſant in dying, aſſured Mr. Curtis, that the roots produced a brighter colour than Madder; and on that account they may be worth trying, eſpecially as the reſt of the plant may be ſucceſsfully uſed in dying yellow.

They were cultivated a few years ſince under the direction of the Committee of Privy Council for Trade. The roots were ſuppoſed on an average to weigh ſeven ounces; and the produce, when dry, to be twelve hundreds and an half on an acre [a].

The roots of moſt of the plants belonging to the natural order of Stellatæ yield more or leſs of a red dye. Not only this ſpecies, but Galium ſylvaticum, Mollugo and Aparine are recommended for this purpoſe. So alſo are Aſperula arvenſis, tinctoria, and cynanchica. See Arduini memoires, 1. p. 55. Steinmeyer diſſ. de Rub. tinct. Memoires de l'Acad. Franc. 1746. p. 104. Memoires des Savans Etrangers. 4. p. 4. Pollich palat. Linn. ſuec. & Act. Holm. 1742. Allioni fl. pedem. &c.

17. Root perennial, branched. Stems ſeveral, rather upright, ſwelled at the joints, roughiſh at the corners, a little hairy, branched; flowering branches oppoſite. Leaves eight, ſometimes ſix only in a whorl, lanceolate or linear-lanceolate, naked. Panicle terminating, dividing into threes. Flowers white. Seeds ſmall [b]. Dr. Stokes adds, that the whorls of leaves are from four to five inches diſtant, and bent back; that the ſerratures are directed towards the point of the leaf and not bowed back as in the other rough-leaved ſpecies; and that his ſpecimen agrees with Mr. Hudſon's deſcription in every reſpect, except that the ſtem is ſmooth. Mr. Hudſon refers to the *G. auſtriacum* of Jacquin (fl. auſtr. 1. t. 80.) as the ſame plant with this, but Dr. Stokes aſſures us that it is quite different.

In meadows and moiſt paſtures. Found in Heydon common, Norfolk, by Mr. Bryant. It flowers in june and july.

18. The whole plant is ſmooth to the touch. Root perennial, creeping. Stem two, three and four feet high, and even more, generally depreſſed, unleſs ſupported, by the weight of the branches, quadrangular (by which it is diſtinguiſhed from the next ſpecies), thickeſt juſt above the joints. Leaves uſually eight on the ſtem, and ſix on the branches, in every whorl, unequal, oblong-ovate, or lanceolate, ſuddenly tapering to a ſharp point, a little hairy on the keel, and at the edges, but not rough to the touch. Flowering branches very much branched, ſuſtaining abundance of white flowers, the four ſegments of which are lanceolate and pointed: they riſe from the whorls of leaves, generally two long and two ſhort ones from each whorl, forming in the whole a panicle. The ſtyle is cloven down to the germ, or more properly there are two ſtyles. One ſeed is generally much larger than the other [c].

Common in hedges and buſhy places: flowering from june to auguſt. It is called *Wild Madder*, and *Great Baſtard Madder*. The roots yield a red dye, like the true Madder, and of a brighter colour: like that alſo, they dye the bones of animals, that feed on them, red.

Varieties.

I have obſerved it ſometimes with flowers of a pale yellow colour.—Scopoli enumerates four varieties: 1. with the bottom leaves emarginate. 2. with the leaves rounded at the end, the nerve ending in a point or prickle. 3. with the leaves toothletted or ſerrulate, each indentation ending in a prickle, which correſponds with our common plant. 4. with the leaves quite entire and reflex, a ſmall alpine plant, only a finger's length. This Dr. Stokes has obſerved on Malvern hills: he is of opinion that *Mollugo montana minor, Gallio albo ſimilis* of Ray, comprehends this variety, as well as the *G. procumbens*. Haller alſo mentions this variety.

19. Stems lofty, weak, ſmooth and even, very obſcurely cornered or roundiſh. Leaves broad-lanceolate, ſcabrous on the keel and about the edge, becoming glaucous. Peduncles elongated, the outmoſt often two-flowered, and near theſe two leaflets. Flowers very minute, nodding before the flowers open [d]. The ſtem thickens at the joints, and is from one to two feet in height. Branches ſingle or many from the ſame joint. Leaves in a whorl from eight to ten, ſometimes only ſix, mucronate; the keel not always ſcabrous. Segments of the corolla very broad, and at the end ſharp: ſtyle very ſhort. Seed round, black, wrinkled; uſually only one in a pair comes to maturity. The whole plant is ſomewhat glaucous; it is ſtouter, the ſtem ſwells more under the whorls of leaves, than in *G. Mollugo*, and the angles are hardly to be obſerved. The root is perennial, yelloviſh on the outſide; and affords a very fine red dye like the laſt.

Native of Germany, Switzerland, and the South of Europe, in woods; flowering from june to auguſt. Cultivated in 1713.

20. Native of the South of Europe. Cultivated in 1759, by Mr. Miller. It flowers in june and july, and is perennial.

21. Perennial. Flowering in june. Introduced in 1778 [e].

22. Perennial. The whole plant ſmooth and even. Stem a foot high. Leaves eight or nine in a whorl, nicely lanceolate, by no means ſtiff [f]. Native of Italy, on monte Baldo, and Ceniſio. It flowers in july. Introduced in 1778, by Mr. Thomas Blackie [g].

23. Perennial. Stems upright, cloſely beſet with very ſhort ſoft hairs. Leaves ſometimes in ſevens, thoſe of the branches fewer, beſet with ſoft hairs, linear, grooved, the edges turned in; the lower ones bent down. There is no appearance of prickles on the ſtem or leaves. Flowering branches oppoſite, one always ſhorter than the other. Peduncles ſmooth.—Auſtria, Profeſſor Jacquin. The plant found by Dr. Stokes in a hedge-row, in a marly ſoil, on the ſide of Red Houſe Lane, near Worceſter, is a variety of *G. Mollugo* [h].

24. Root ſmall, very ſlender, creeping. Stems from a ſpan to a foot in length, and more, brittle, ſlender, proſtrate, a little hairy at bottom. Leaves quite entire, ending in a fine long prickle; the lower ones ſomewhat rough, with hairs about the edge, the upper ones ſmooth, but ſometimes they are all hairy. Panicles terminating and axillary, ſhort; peduncles branched, not very leafy, biſid or triſid. Corolla white. Style very deeply cloven. Seeds minute, round, cloven [i].

Native of France, Germany and Switzerland, where Haller informs us it is frequent by way ſides, in corn-fields and ſtony places: it is alſo found in the Alps, and there becomes a more humble creeping plant. He mentions ſeveral varieties.

25. In ſtature this approaches very near to *G. rubrum*. Native of Paleſtine [k].

26. Root perennial, ſomewhat creeping, branched. Stems ſlender, weak, proſtrate, gloſſy. Leaves five or ſix, gloſſy, glaucous underneath, hardly ſcabrous on the edge, the lower ones turned back. Flowers white, in ſubtriſid, ſmall umbels [l].—According to Haller and Jacquin, there are eight leaves in a whorl—according to Allioni ſix or ſeven, ſerrate on the edge—according to Krocker, eight or even nine in the lower ones, but five or ſix in the upper ones;—Scopoli aſſigns only ſix to the lower whorls, four to

[y] Lewis. [z] Withering and Lightfoot. [a] Young's annals, vol. 18. [b] Hudſon. [c] Withering, Stokes in With. Relhan, Ray, Pollich, Scopoli, Haller. [d] Linn. ſpec. & ſyſt. [e] Hort. kew. [f] Linn. ſpec. [g] Hort. kew. [h] Stokes in With. [i] Haller, Pollich, Krocker. [k] Linn. ſpec. [l] Ibid.

the upper one, and two only to those on the branches.—Haller says that it resembles n. 24.—that the stem is upright; the leaves glaucous, thicker, terminating in shorter awns; the upper ones fewer, broad, ovate-lanceolate. The top of the stem, and the branches subdivided, bearing flowers of four times the size, in upright bunches.

Native of the South of Europe, Tartary and Siberia, in mountain woods and fissures of rocks. It flowers in our gardens from june to september, and was cultivated in 1713[a].

27. Perennial. This is an elegant species covered with a glaucous bloom; when this bloom is wiped off, the plant is of a shining, not a dark green. Stems obscurely quadrangular. Leaves of a long elliptic form, wider at the end, and terminating in a remarkable white prickle. A panicle of flowers terminates the stem and branches, the extreme peduncles bearing usually three flowers, one of which is abortive. Seeds large, dirty white, smooth, but when full ripe wrinkled. It is not the *glaucum* of Linnæus, the linear leaves of which are longer, not spreading, not serrulate-aculeate; the branches also in that are terminated rather with an umbel than a panicle of flowers. Native of Piedmont and Dauphiné[b].

28. Perennial. Stems eighteen inches high, smooth, sharply quadrangular. Branches opposite, one longer than the other. Leaves eight at bottom, diminishing till they come to two, or even one; truly rigid, not soft and flexible, smooth, but not shining. Pedunckes very much branched, capillary, longer than the leaf, divaricate. Segments of the corolla large, white and awned. Seeds slightly wrinkled, but neither hairy nor rough; the colour of them black[c].

Native of the county of Nice, Provence and Dauphiné.

29. Stem upright, very much branched, and so leafy that the leaves can hardly be numbered. They are usually in eights, smooth, and keeled underneath. Branches ascending, and from their axils innumerable pedunckes, above the leaves upright, sustaining few flowers: these and the stems are dark purple; and the roots dye red[d].—By Lago Lugano: near Ripa and Chiavenna: in the counties of Nice, Montferrat, &c.—Perennial.

30. Root perennial, slender. The whole plant pale green. Stems slender, prostrate, near a foot in length, rough with small prickles. Leaves on the stem six or seven in a whorl, on the branches four or five, bent down, lanceolate, quite entire, dusky green, smooth, but the edge very rough with prickles, and a little prickle at the end; they are three lines in length, and half a line in breadth; the upper leaves are in pairs. The flowers are very small, of a pale purple colour (fusco-rubri, *Scop.*) or white, disposed in panicles at the end of the stem and branches[e]. This differs from the foregoing species, with which it seems to have been confounded by several authors, by the leaves not being elliptic, nor spreading out; also by the shortness of the pedunckes, and its manner of flowering: for in *G. purpureum* the flowers are terminating, rather panicled; purple, not reddish brown[f].

Native of the Palatinate, Silesia, Carniola, and Italy. It flowers in july and august.

31. Root perennial, long, slender, dark purple. Stems a foot or eighteen inches in height, obscurely quadrangular, stout, much branching at top; the lower part smooth, the upper slightly hairy: or, according to English Botany, rough to the touch, though not hairy. Leaves lanceolate or oval-lanceolate, rough to the touch, quite entire, blunt, bent back at the edges, having a strong nerve along the middle, and a smaller one on each side, at the end of each branch a pair of small stipular leaves, oval or ovate, and slightly hairy. Flowers copious, in a terminating panicle, formed of racemes or corymbs growing gradually smaller. Corolla white, with ovate segments. Styles two. Fruit covered with long, soft whitish hairs, slightly curved upwards.

Native of Lapland, Sweden, Silesia, Switzerland, Carniola, Britain; as in the mountains of Westmoreland and Wales: near Pooley bridge by Ullswater, in Cumberland: near the ferry at Winander meer. In the county of Durham. In Scotland not unfrequent on rocks by the sides of rivers and lakes. It flowers in july and august.

This is one of the species whose roots afford a beautiful red dye. The process is thus described by Haller.—The roots are gathered in spring, they are ground with malt dust, and infused in small beer, the woollen yarn is macerated, and then boiled in this liquor. Gunner adds that the yarn is first dyed yellow in a decoction of birch leaves.

32. Perennial. Native of North America. It flowers in june and july. Introduced in 1778, by John Fothergill, M. D[g].

33. Root perennial, slender, creeping, cinnamon-coloured. Stem weak, a foot long, slightly grooved; branches alternate, green at bottom, pubescent, with very short hairs, and leafy; frequently purplish above, naked and jointed. Leaves subpetioled, four or very seldom five in a whorl, spreading, broad, with very short hairs on the nerves and at the edges; towards the top of the stem, where it terminates in two or three almost dichotomous pedunckes, is placed a pair of lanceolate leaves. Pedunckes naked, an inch or two inches in length, bifid, seldom trifid, diverging, each terminating in a solitary flower, and filiform. Corolla white. Seeds white, bearded with long hairs[h]. See Asperula lævigata.

Native of Silesia, Switzerland, Savoy, Austria, &c. It flowers in july and august.

34. Root perennial. Stem brachiate, rough with hairs, very much branched; the last branches dichotomous. Leaves in fours, rarely fives; the upper floral ones frequently in pairs; lanceolate-ovate, rough, with hairs on both sides, the uppermost subpetioled. Pedunckes capillary, shorter than the leaves, usually one-flowered, seldom bifid. Flowers small[i].

Observed in the Levant, by Schreber.—If it be Gouan's plant, it is also native of Montpellier, the Pyrenees, and the County of Nice; but according to Gouan the leaves are eight in a whorl.

35. Whorls of leaves very distant; flowers dark purple; seed lanuginose. Native of Virginia and Maryland.

36. Stems variously bent and twisted, and some what woody; branches straight, stiff, herbaceous, rough with white villose hairs, as are also the leaves, pedunckes and germs. Leaves stiff, upright, the length of the internodes, sparingly hairy, green. Pedunckes longer than the leaves, subdivided, forming a kind of umbel of few flowers, capillary.—Native of the islands of the Archipelago[k].

37. Root annual. Stem four feet high or more, weak, and supporting itself on other plants, brittle, jointed, the joints villose at the base; the angles are set with pellucid prickles pointing downwards; it is very much branched, and the branches are opposite. Leaves six or eight in a whorl (eight or ten, *Lin.* four to seven or more, *With.* six to eight, *Hall. Pill. Kroch.* seven, *Bauh. Ray.*—eight on the lower, six on the upper whorls of the stem, on the branches fewer, from six to three, two and even one), lanceolate-linear, terminating in an awn, which is frequently purplish, the upper surface scabrous, the lower smooth, the edges and keel set with prickles pointing backwards. Flowers few, small, on rough pedunckes. Calyx none. Corolla whitish, scarcely longer than the germ, divided to the base into four ovate-acute segments. Styles two, shorter than the corolla,

[a] Hort. kew. [b] Haller. [c] Allioni. [d] Pollich. [e] Ibid. & Gerard. [f] Allioni.

[g] Hort. kew. [h] Krocker. [i] Ibid. [k] Linn. mant.

corolla, ſtanding wide aſunder. Fruit ſet with hooked briſtles [r].

Common in hedges, and cultivated grounds; flowering from may and june through the ſummer and part of the autumn.

Its well-known property of adhering to whatever it comes in contact with, acquired it the names of *Cleavers*, *Clevers*, *Clivers*, and *Catchweed* or *Scratchweed*; from the ſame idea it had the more elegant appellation of *Philanthropon* among the Greeks and Romans; from its roughneſs it has been called *Hariff*, or rather *Hairough*: and from being a favourite food or medicine of Geeſe, *Gooſe-graſs*, *Gooſe-ſhare*, and *Geeſing-weed*.

Linnæus informs us that they uſe the ſtalks in Sweden as a filtre to ſtrain their milk through. Dioſcorides relates that the ſhepherds made the ſame uſe of it in his time; and certainly it is no bad thing to take out hairs from the milk, where a ſieve is not at hand. It is reckoned to purify the blood, and for that purpoſe the tops are an ingredient in ſpring broth. The expreſſed juice of the herb, taken to the amount of four ounces or a quarter of a pint, night and morning, during ſeveral weeks, is very efficacious in removing many of thoſe cutaneous eruptions, which are called, although improperly, ſcorbutic. It has been much celebrated in ſcrophulous and cancerous ſores, but experiments made in our hoſpitals have not turned out in its favour. The ſeeds have been ſubſtituted for coffee. The roots, like moſt of the genus, will dye red, and eaten by birds, have tinged their bones of that colour. It is a troubleſome weed, particularly in young quick-ſet hedges, which it will entirely overgrow and choke. Linnæus ſays it is very apt to infeſt their crops of peas. Being an annual weed, it is eaſily deſtroyed, if it be cut or plucked up early, for it begins to ſeed in june.

38. Root annual. Stems a foot high, weak, ſcabrous backward. Leaves in ſevens, lanceolate, mucronate, ſcabrous, eſpecially on the edge. Flowering-branches oppoſite, ſhorter. Peduncles naked, two or three-flowered. Corollas yellow, ſmall [s]. See n. 11.—If it be Haller's n. 726. The corolla is white, and very ſmall; the fruit hiſpid, with white hairs.

39. This forms a tuft; the ſtems are not more than a finger's length; branches alternate: from the laſt whorl they produce two-flowered peduncles. Flowers pale yellow. Fruits dirty white.—Native of Monte Ceniſio [t].

40. Suppoſed to be a variety of V. Aparine. Parkinſon ſays it differs from *Aparine lævis* only in having the ſeed rough like unto a Coriander Comfit.—Ray, that the leaves are ſmooth, and the fruits warted, but not lappaceous or tenacious.—Haller alſo conſiders it as a variety of *A. ſem. lævi* of Vaillant, and A. Valantia of Linnæus, with the ſurface of the fruit a little more rough. He affirms that it has a quadrifid fertile flower ſitting between two trifid male ones. *n.* 725.—Vaillant ſays that the fruit of his *A. ſem. lævi* is only ſhagreened, by which it differs chiefly from *A. ſem. coriandri* of *Parkinſon*, and by the ſurface of its leaves, which are almoſt ſmooth.

41. Native of New Zealand [u].

42. Root annual. Stem ſeveral, aſcending, a finger or a hand in height, ſmooth, even, made four-cornered by a pale decurrent line, branched from all the lower axils, ending at length towards the top in oppoſite peduncles, an inch long. In a rich ſoil the ſtems are frequently a ſpan high, and ſpreading. Lower leaves in fours, ſmall, ovate; upper in ſixes, linear-lanceolate, only half the length of the internodes, ſmooth, having minute prickles on the edge turned towards the tip; uppermoſt in ſevens; floral-leaves in threes, finally in pairs. Peduncles from all the axils of the leaves, branches, and upper part of the ſtem, oppoſite, filiform, by threes. The laſt pedicels two-flowered. Corolla yellowiſh-white. Seeds minute, viſcid.

This is allied to G. ſpurium only in the number of leaves; the ſtem is not weak, and in appearance it does not differ from G. Aparine; beſides it is leſs, the prickles on the edge of the leaves are turned towards the tip not the baſe, the angles of the ſtem and the keel of the leaves are not prickly and rugged, and the ſeeds are viſcid. Galium lucidum of Allioni has a ſtricter, higher, ſhining ſtem, the leaves longer and narrower, the edge quite even, and the flowers larger. G. cinereum of the ſame author is more nearly allied to this as to the leaves, but differs in its glaucous colour, in being leſs branched, in having larger ſeeds, and in other circumſtances. Native of Tunis, in the mountains.

43. Stems weak, a foot and half high or more, ſimple, ſmooth, even. Whorls very remote, eight or nine-leaved: leaves an inch and half long, mucronate, ſmooth, even except at the edge. Univerſal peduncles axillary, oppoſite, ſolitary, ſpreading very much, three inches long, filiform: partial peduncles in threes, twice or three times trichotomous, faſtigiate, capillary. There are two ſmall leaves below the partial peduncles. Seeds minute. Perhaps not different from G. hierofolymitanum.

44. Stem herbaceous, weak, half a foot high, prickly backwards at the corners, with equal joints. Leaves having minute prickles at the edge, the upper ones very minute prickles curved in on each ſide. Peduncles three from the ends of the branchlets, bifid. Seeds as in G. Aparine, from which it differs in the ſize, number and form of the leaves.

45. Stem the thickneſs of a pigeon's quill, erect, branched, a cubit in height, pubeſcent, unarmed, purpliſh brown at the joints, the internodes a ſpan in length. Leaves ſeſſile, commonly in ſevens, mucronate, ſcarcely ſerrulate at the edge, ſmooth above, villoſe underneath, eſpecially on the keel. Fruit hiſpid. Native of Smyrna.

46. Stems ſeveral filiform, a hand and ſometimes a finger high, erect, rugged at the corners below, but even above, branched at the baſe, dichotomous or trichotomous at top. Lower leaves in fours, petioled, obovate, ſmall; the middle ones in ſixes, a little longer, marked with two lines, oblong, ſharp at both ends; the upper ones, under the branches and univerſal peduncles in ſixes or ſevens, briſtle-ſhaped, the length of the internodes; all nearly even, having very minute cilias along the edge, ſcarcely viſible without a magnifier. Peduncles terminating, capillary, in threes, bifid: pedicels one-flowered: two briſtle-ſhaped leaflets at the baſe of the peduncles. Flowers purple. Fruit minute, whitiſh-hiſpid. Native of the dry mountains of Tunis; and of Spain, but not ſo common there. It has many points in common with G. parifienſe. Perhaps it may not be different from G. tuneranum of Poiret; but in that there are nine or ten leaflets in a whorl, and the peduncles are hairy-rough [x].

47. The root is a ſmall, oblong, irregularly ſhaped, white, farinaceous tuber. Stem herbaceous, a foot and half high, rufous, procumbent, ſimple. Leaflets four or five together, lanceolate, quite entire, ſmooth, glaucous. Flowers white, on longiſh, one-flowered, heaped, axillary peduncles. Fruit roundiſh, rough. It is cultivated in China and Cochinchina for the roots, which are eaten boiled, either whole or in meal. They are eſteemed to be very ſalutary [y].

48. Root perennial, creeping, ſlender. Stems branched only at the baſe, weak and ſupporting themſelves on buſhes, quadrangular, very hairy, jointed; having at every joint four ovate, entire, ſoft, hairy leaves, from the axils of theſe all the way up the ſtem ariſe ſeveral ſlender, forked, many-flowered peduncles, each furniſhed with two ſmall leaves at the firſt diviſion. The flowers are yellow, formed exactly like the Gahums, except that ſome are only

[x] Vahl. [y] Loureiro.

male,

male, and some of the hermaphrodites are five-cleft. The style is deeply cloven, and there are two germs, one of which is generally abortive. The fruit is globose, smooth, and sheltered by the reflex leaves[e].

This, and some other of the Linnean Valantias (glabra, articulata, Aparine) belong to the Galiums, several of which (Mollugo, Aparine, parisiense) have male flowers mixed with the perfect ones. Wiggers had a specimen of Valantia in which all the flowers were hermaphrodite; on the contrary I have frequently sought in vain for a single perfect flower; but barrenness is not uncommon in plants that run much and freely at the root: such plants may be compelled to become fertile by confining the roots.

Crosswort is not uncommon about hedges and in thickets, flowering early in summer.]

PROPAGATION AND CULTURE.

Most of these plants being destitute of beauty, and being subject to spread, and over-run whatever plants grow near them, are seldom cultivated except in botanic gardens. The perennial sorts may easily be propagated, by parting their roots either in spring or autumn: and they will grow in almost any soil and situation. [If the annual sorts are permitted to scatter their seeds, they will maintain themselves in a garden without any culture, except that of preventing other weeds from overgrowing them. The common Goosegrass (G. Aparine) propagates itself prodigiously, by the adhesion of its fruits to the hairy coats of cattle, &c.

If it should be thought adviseable to propagate the Galium verum for the use of the roots in dyeing, the best soil is a sandy loam, heavy soils will not answer. Prepare the land as for flax. Sow four pounds of seed on an acre. In april hoe out the plants to six inches square. The crop will require three or four hoeings more the first season. In may or june take up as many plants as will leave the rest at the distance of one foot square. In march following take up again as many as will leave the rest standing at two feet square: and in the fourth take up the whole crop in march; keeping it all the while clean from weeds[f].

SPECIES.

1. Galopina circæoides.

Thunb. nov. gen. t. *Lin. syst.* 166.

Anthospermum Galopina. *Thunb. prodr. cap.* 32.

DESCRIPTION, &c.

Root annual. Stem herbaceous, round, red, smooth, seldom branched, erect but weak, about two feet high. Branches alternate, spreading, resembling the stem. Leaves opposite, petioled, oblong, acute, entire, smooth, pale underneath, an inch or a little more in length. In the axils of the leaves are others, similar, but smaller. Flowers terminating, in a loose diffused panicle. Pedincles and pedicels opposite, capillary, smooth, with two opposite, bristle-shaped bractes. Native of the Cape of Good Hope.

[e] Engl. bot. [f] Young's Annals, vol. 18

In the systematic arrangement it has its place before Aphanes; from which it differs in having the filaments inserted into the receptacle, and a superior corolla. It differs from Galium in having no calyx, and two styles[g].

Thunberg, who constituted this genus, has thought fit, in his Prodromus Plantarum Capensium, to sink it, and make this plant a species of Anthospermum.

GANDOLA. See *Basella.*

GANGITIS. See *Nardus.*

GANIA. See *Corchorus.*

GANITRUS. See *Elæocarpus.*

GARB. See *Salix babylonica.*

GARBANZO. See *Cicer arietinum.*

To that article we may add, that this pulse is highly esteemed in Spain, as fodder for cattle, and at the table in soups and other dishes, but principally with that standard dish in all families, the *olio*.

The Garbanzo plant has a very inconsiderable root, not penetrating far into the ground, and therefore not impoverishing the soil; its branches are numerous, and the large sort throws out shoots three feet long: it varies in colour, white, reddish, or rather gray; and the seed of each is of the same colour respectively. Each pod contains but one seed, or at most two; not round, but rather pointed; whence it is compared to a sheep's head, and the trivial name *arietinum*. In Castile they say that the best sort has the surface wrinkled like the face of an old woman, the broad back of a porter, and the bill of a parrot; the colour also should be, not white, but of a pale hue; and it should be light, soft and fat.

This pulse does not succeed so well in the hotter parts of Spain as in the cold northern districts of Fuente Sauco, Mentrida, and others. It is sowed in the same manner as other pulse, and generally in open fields. A soft rich soil is best for the Garbanzo, but a stiff clay is not unsuitable to it. The Spaniards have a proverb, that rain never hurts Garbanzos. There are two principal sorts, or rather varieties, the large or winter, and the small or summer Garbanzo. The former should be sown the first week in october, that it may acquire a good root, and spread out luxuriantly for fodder. The latter must be sown about the end of february.

The consumption of the Garbanzo is great in Spain to fodder cattle, and it is reckoned tolerably nutritive. It is used either by feeding it on the ground, by cutting it green, and giving it to them in the stall or stable, which is the best, or dried after the manner of hay. The large sort furnishes an early fodder for cattle, sheep and lambs, at a time when no other is to be had. It is a good preparation for other crops, because it is destructive of weeds, and shades the surface of the ground.[h]]

DESCRIPTIONS, *&c.*

1. The Mangoſtan riſes with an upright ſtem near twenty feet high, ſending out many branches on every ſide, which are placed oppoſite, and ſtand oblique to each other, and not at right angles; the bark of the branches is ſmooth, of a gray colour, but on the tender ſhoots it is green, and that of the trunk is of a darker colour, and full of cracks: the leaves are entire; they are ſeven or eight inches long, and about half as much in breadth in the middle, gradually diminiſhing to both ends, of a lucid green on their upper ſide, and of an olive colour on their under, having a prominent midrib through the middle, with ſeveral ſmall veins running from that to both ſides of the leaf. The flower is like that of a ſingle Roſe, compoſed of four roundiſh petals, which are thick at their baſe, but are thinner toward their ends; they are of a dark red colour. The fruit is round, the ſize of a middling Orange; the top is covered by a cap, which was the ſtigma on the top of the ſtyle, and is indented in rays to the number of ſix or ſeven, which are obtuſe. The ſhell of the fruit is like that of the Pomegranate, but ſofter, thicker, and fuller of juice; it is green at firſt, but changes to a dark brown, with ſome yelloviſh ſpots; the inſide of the fruit is of a Roſe colour, and divided into ſeveral parts by thin partitions, as in Oranges, in which the ſeeds are lodged, ſurrounded by a ſoft juicy pulp of a delicious flavour, partaking of the Strawberry and the Grape, and is eſteemed one of the richeſt fruits in the world: the trees naturally growing in the form of Parabolas, and the branches being well garniſhed with large ſhining green leaves, they have an elegant appearance, and afford a kindly ſhade in hot countries, therefore are worthy of cultivation in all thoſe countries where there is warmth enough to ripen the fruit.

[According to Dr. Garcin, this tree grows to about ſeventeen or eighteen feet high, with a ſtraight tower ſtem like a Fig, having a regular head in form of an oblong cone, compoſed of many branches and twigs, ſpreading out equally on all ſides, without leaving any hollow. The leaves are oblong, pointed at both ends, entire, ſmooth, of a ſhining green on the upper ſide, and of an olive on the back. The colour of the flower reſembles that of a *Roſe*, only deeper and leſs lively. The two upper leaflets of the calyx are ſomething larger than the lower ones, they are greeniſh on the outſide, and of a fine deep red within, the red of the upper ones more lively than that of the lower ones. The calyx is ſupported by a green pedicel, which conſtantly comes out at the end of a twig above the laſt pair of leaves. The fruit is from an inch and half to two inches in diameter: the rind is commonly a quarter of an inch thick, and a little like that of a pomegranate, but ſofter, thicker, and fuller of juice, of a dark brown purple on the outſide, mixed with a little gray and dark green: on the inſide of a roſe-colour. The juice is purple. The ſegments into which it is divided are unequal in ſize, and uncertain in number; they are always the ſame in number with the rays of the ſtigma, and they do not adhere to each other. The ſegments are white, a little tranſparent, fleſhy, membranous, full of juice: and each incloſes a ſeed of the figure and ſize of an almond ſtripped of its ſhell, having a protuberance on one of its ſides, and covered with two thin ſkins, the outermoſt of which ſerves for a baſis to the filaments and membranes of which the pulp is compoſed. Their ſubſtance comes very near to that of Cheſtnuts, as to their conſiſtency, colour, and aſtringent quality.

It is eſteemed the moſt delicious of the Eaſt-Indian fruits, and a great deal of it may be eaten without any inconvenience: it is the only fruit which ſick people are allowed to eat without ſcruple[a]. It is given with ſafety in almoſt every diſorder; and we are told that Dr. Solander, in the laſt ſtage of a putrid fever at Batavia, found himſelf inſenſibly recovering, by ſucking this delicious and refreſhing fruit. The pulp has a moſt happy mixture of the tart and ſweet, and is no leſs ſalutary than pleaſant, for which reaſon, in hot climates, it is allowed, with the ſweet orange, in any quantity, to thoſe who are afflicted with fevers, either of the putrid or inflammatory kind. The dried bark is uſed with ſucceſs in the dyſentery and tenеſmus; and an infuſion of it is eſteemed a good gargle for a ſore mouth or ulcers in the throat. The Chineſe dyers uſe this bark for the ground or baſis of a black colour, in order to fix it the firmer.

Native of the Moluccа iſlands, whence it has been tranſplanted to Java and Malacca. The head is ſo fine and regular, and the leaves ſo beautiful, that it is looked upon at Batavia as the tree moſt proper for adorning a garden, and affording an agreeable ſhade[b].

Mr. Miller aſſerts that he received perfect ſpecimens by Mr. Robert Millar, who gathered them near Tolu, in New Spain. The ſpecimens do not appear in Mr. Miller's herbarium, now in the poſſeſſion of Sir Joſeph Banks, ſo that we cannot decide the point with certainty; we may however preſume that Mr. Miller was miſtaken, the Mangoſtan never having been found in America by any traveller before or ſince the time of Mr. Robert Millar; and it is probable that Mr. Philip Miller might miſtake ſome ſpecies of Clуsia for the Mangoſtan; the Cluſia being common in South America, and bearing ſome reſemblance of this tree.

2. This is not a lofty tree, but it has an elegant ſpreading head. Leaves oppoſite, on ſhort ſtrong petioles, five or ſix pairs, narrower and ſharper than thoſe of the firſt ſort, ſeven or eight inches long, and more than three fingers broad, thick and ſtrong, but leſs ſo than in the common Mangoſtan; the parallel tranſverſe ribs are ſo fine as ſcarcely to be diſtinguiſhed; in a young tree they are nine inches and a half long, and three and a half or four inches broad, entirely ſmooth and even. The fruit reſembles that of the common Mangoſtan, but ſometimes grows to a larger ſize; it is of a yellowiſh red or ſaffron colour, like the Pomegranate, and is not crowned with a ſtar, but with a little crown, which is hollowed above, and broader there than at

[a] *Garcin in Phil. tranſ.* and *Ellis.*
[b] Ellis and Cook's voyage.

its

its origin.—Native of the iſland of Celebes about Macaſſar, whence it has been tranſplanted into Amboina and Java, where however it ſeldom bears ripe fruit.

3. The trunk of this tree is lofty, but not very thick; it is covered with a black bark, adhering firmly to the wood; the branches extend wide, and divide into many ſhort branchlets, which have a pair of leaves at each joint; theſe are large, from eleven to fifteen inches long, and four broad, but on old trees ſhorter, ſmooth, firm and ſhining, having a thick midrib beneath, but above ſmooth and grooved; petioles thick and ſhort, frequently ſo curved in that the lower ſide of the leaf becomes the upper one. The flower comes out from the branch between the upper leaves, hanging on an incurved peduncle, having the form of a ſmall Roſe, but of a yellow colour. Fruit ſolitary, growing cloſe to the branch, the ſize of a Plum, crowned by a ſort of wart like the head of a nail; it is of a dulky brown or ſmoky colour on the outſide, and within it has a mucoſe pulp, in which lie a few ſeeds in ſhape of a half moon. It has a reſinous ſmell when freſh. The wood is heavy and very hard like horn, whence Rumphius names it *Lignum cervinum*; it is uſed for the handles of tools, and the young trees in building, the older ones being too hard to work. Native of Amboina, in high remote mountains.]

PROPAGATION AND CULTURE.

As there are but few of the ſeeds which come to perfection (for the greateſt part of them are abortive) ſo moſt of thoſe which have been brought to Europe have failed; therefore the ſureſt way to obtain the plants, is to ſow the ſeeds in tubs of earth in the country, and when the plants have obtained ſtrength, they may be brought to Europe; but there ſhould be great care taken in their paſſage, to ſcreen them from ſalt water and the ſpray of the ſea, as alſo not to give them much water, eſpecially when they are in a cool or temperate climate, for theſe plants are very impatient of wet. When the plants arrive in Europe, they ſhould be carefully tranſplanted, each into a ſeparate pot, filled with light kitchen-garden earth, and plunged into the tan-bed, obſerving to ſhade them from the ſun till they have taken new root; then they muſt be treated in the ſame manner as other tender plants from hot countries.

It may be increaſed here by cuttings in the ſame manner as is directed for Gardenia.

Leaves lanceolate, veinleſs; peduncles one-flowered, drooping.]

DESCRIPTIONS, *&c.*

1. The Mangoſtan riſes with an upright ſtem near twenty feet high, ſending out many branches on every ſide, which are placed oppoſite, and ſtand oblique to each other, and not at right angles; the bark of the branches is ſmooth, of a gray colour, but on the tender ſhoots it is green, and that of the trunk is of a darker colour, and full of cracks: the leaves are entire; they are ſeven or eight inches long, and about half as much in breadth in the middle, gradually diminiſhing to both ends, of a lucid green on their upper ſide, and of an olive colour on their under, having a prominent midrib through the middle, with ſeveral ſmall veins running from that to both ſides of the leaf. The flower is like that of a ſingle Roſe, compoſed of four roundiſh petals, which are thick at their baſe, but are thinner toward their ends; they are of a dark red colour. The fruit is round, the ſize of a middling Orange; the top is covered by a cap, which was the ſtigma on the top of the ſtyle, and is indented in rays to the number of ſix or ſeven, which are obtuſe. The ſhell of the fruit is like that of the Pomegranate, but ſofter, thicker, and fuller of juice; it is green at firſt, but changes to a dark brown, with ſome yelloviſh ſpots; the inſide of the fruit is of a Roſe colour, and divided into ſeveral parts by thin partitions, as in Oranges, in which the ſeeds are lodged, ſurrounded by a ſoft juicy pulp of a delicious flavour, partaking of the Strawberry and the Grape, and is eſteemed one of the richeſt fruits in the world: the trees naturally growing in the form of Parabolas, and the branches being well garniſhed with large ſhining green leaves, they have an elegant appearance, and afford a kindly ſhade in hot countries, therefore are worthy of cultivation in all thoſe countries where there is warmth enough to ripen the fruit.

[According to Dr. Garcin, this tree grows to about ſeventeen or eighteen feet high, with a ſtraight ſlender ſtem like a Fir, having a regular head in form of an oblong cone, compoſed of many branches and twigs, ſpreading out equally on all ſides, without leaving any hollow. The leaves are oblong, pointed at both ends, entire, ſmooth, of a ſhining green on the upper ſide, and of an olive on the back. The colour of the flower reſembles that of a *Roſe*, only deeper and leſs lively. The two upper leaflets of the calyx are ſomething larger than the lower ones, they are greeniſh on the outſide, and of a fine deep red within, the red of the upper ones more lively than that of the lower ones. The calyx is ſupported by a green pedicel, which conſtantly comes out at the end of a twig above the laſt pair of leaves. The fruit is from an inch and half to two inches in diameter: the rind is commonly a quarter of an inch thick, and a little like that of a pomegranate, but ſofter, thicker, and fuller of juice, of a dark brown purple on the outſide, mixed with a little gray and dark green: on the inſide of a roſe-colour. The juice is purple. The ſegments into which it is divided are unequal in ſize, and uncertain in number; they are always the ſame in number with the rays of the ſtigma, and they do not adhere to each other. The ſegments are white, a little tranſparent, fleſhy, membranous, full of juice: and each incloſes a ſeed of the figure and ſize of an almond ſtripped of its ſhell, having a protuberance on one of its ſides, and covered with two thin ſkins, the outermoſt of which ſerves for a baſis to the filaments and membranes of which the pulp is compoſed. Their ſubſtance comes very near to that of Cheſtnuts, as to their conſiſtency, colour, and aſtringent quality.

It is eſteemed the moſt delicious of the Eaſt-Indian fruits, and a great deal of it may be eaten without any inconvenience: it is the only fruit which ſick people are allowed to eat without ſcruple *. It is given with ſafety in almoſt every diſorder; and we are told that Dr. Solander, in the laſt ſtage of a putrid fever at Batavia, found himſelf inſenſibly recovering, by ſucking this delicious and refreſhing fruit. The pulp has a moſt happy mixture of the tart and ſweet, and is no leſs ſalutary than pleaſant, for which reaſon, in hot climates, it is allowed, with the ſweet orange, in any quantity, to thoſe who are afflicted with fevers, either of the putrid or inflammatory kind. The dried bark is uſed with ſucceſs in the dyſentery and tenеſmus; and an infuſion of it is eſteemed a good gargle for a ſore mouth or ulcers in the throat. The Chineſe dyers uſe this bark for the ground or baſis of a black colour, in order to fix it the firmer.

Native of the Moluccа iſlands, whence it has been tranſplanted to Java and Malacca. The head is ſo fine and regular, and the leaves ſo beautiful, that it is looked upon at Batavia as the tree moſt proper for adorning a garden, and affording an agreeable ſhade *.

Mr. Miller aſſerts that he received perfect ſpecimens by Mr. Robert Millar, who gathered them near Tolu, in New Spain. The ſpecimens do not appear in Mr. Miller's herbarium, now in the poſſeſſion of Sir Joſeph Banks, ſo that we cannot decide the point with certainty; we may however preſume that Mr. Miller was miſtaken, the Mangoſtan never having been found in America by any traveller before or ſince the time of Mr. Robert Millar; and it is probable that Mr. Philip Miller might miſtake ſome ſpecies of Clusia for the Mangoſtan; the Cluſias being common in South America, and bearing ſome reſemblance of this tree.

2. This is not a lofty tree, but it has an elegant ſpreading head. Leaves oppoſite, on ſhort ſtrong petioles, five or ſix pairs, narrower and ſharper than thoſe of the firſt ſort, ſeven or eight inches long, and more than three fingers broad, thick and ſtrong, but leſs ſo than in the common Mangoſtan; the parallel tranſverſe ribs are ſo fine as ſcarcely to be diſtinguiſhed; in a young tree they are nine inches and a half long, and three and a half or four inches broad, entirely ſmooth and even. The fruit reſembles that of the common Mangoſtan, but ſometimes grows to a larger ſize; it is of a yelloviſh red or ſaffron colour, like the Pomegranate, and is not crowned with a ſtar, but with a little crown, which is hollowed above, and broader there than at

* Garcin in Phil. tranſ. and Ellis.

* Ellis and Cook's voyage.

its origin.—Native of the iſland of Celebes about Macaſſar, whence it has been tranſplanted into Amboina and Java, where however it ſeldom bears ripe fruit.

3. The trunk of this tree is lofty, but not very thick; it is covered with a black bark, adhering firmly to the wood; the branches extend wide, and divide into many ſhort branchlets, which have a pair of leaves at each joint; theſe are large, from eleven to fifteen inches long, and four broad, but on old trees ſhorter, ſmooth, firm and ſhining, having a thick midrib beneath, but above ſmooth and grooved; petioles thick and ſhort, frequently ſo curved in that the lower ſide of the leaf becomes the upper one. The flower comes out from the branch between the upper leaves, hanging on an incurved peduncle, having the form of a ſmall Roſe, but of a yellow colour. Fruit ſolitary, growing cloſe to the branch, the ſize of a Plum, crowned by a ſort of wart like the head of a nail; it is of a dulky brown or ſmoky colour on the outſide, and within it has a mucoſe pulp, in which lie a few ſeeds in ſhape of a half moon. It has a reſinous ſmell when freſh. The wood is heavy and very hard like horn, whence Rumphius names it *Lignum corneum*; it is uſed for the handles of tools, and the young trees in building, the older ones being too hard to work. Native of Amboina, in high remote mountains.*]

PROPAGATION AND CULTURE.

1. As there are but few of the ſeeds which come to perfection (for the greateſt part of them are abortive) ſo moſt of thoſe which have been brought to Europe have failed; therefore the ſureſt way to obtain the plants, is to ſow the ſeeds in tubs of earth in the country, and when the plants have obtained ſtrength, they may be brought to Europe; but there ſhould be great care taken in their paſſage, to ſcreen them from ſalt water and the ſpray of the ſea, as alſo not to give them much water, eſpecially when they are in a cool or temperate climate, for theſe plants are very impatient of wet. When the plants arrive in Europe, they ſhould be carefully tranſplanted, each into a ſeparate pot, filled with light kitchen-garden earth, and plunged into the tan-bed, obſerving to ſhade them from the ſun till they have taken new root; then they muſt be treated in the ſame manner as other tender plants from hot countries.

It may be increaſed here by cuttings in the ſame manner as is directed for Gardenia.

GARDENIA. *(So named by Ellis, in honour of Alexander Garden, M. D. of Charleſtown in Carolina.)*

Ellis. *Lin. gen. n. 296. Reich. 320 Schreb. 416. Thunb. diſſ. 6. Lin. ſuppl. 23. Gartn. t. 28. Joſſ. 201.*—Jaſminum. *Mill. fig. t. 180.*

Thorns oppoſite, both they and the flowers ſhorter than the leaves, branches ſmooth.

DESCRIPTIONS, *&c.*

[1. Stem decumbent, ſmooth, thickneſs of a reed, about a foot high, putting out roots at bottom. Branches oppoſite, tubercled with rudiments of leaves, flexuoſe, upright. Leaves aſſembled at the ends of the branches, oppoſite, ſubſeſſile, entire, marked with parallel nerves, ſmooth, upright, from an inch to two inches in length. Stipules between the leaves, ovate, obtuſe, ſheathing, membranaceous. Flowers ſolitary, ſubſeſſile, at the ends of the branches. Calyx angular, ſmooth, five or ſix-parted: diviſions lanceolate, vertical, only half the length of the tube of the corolla, which is white, leathery, and uſually double: the diviſions of the border oblong, obtuſe, flat. It differs from *G. florida* in being many times ſmaller, with a ſlender, decumbent, rooting ſtalk, and narrow leaves, of an elliptic or lanceolate form. Drawn to a point at each end. It is commonly cultivated in Japan, where it flowers in june and july [a].]

2. Stem large and woody, ſending out many branches, which are firſt green, but afterwards the bark becomes gray and ſmooth; the branches come out by pairs oppoſite, and have ſhort joints; the leaves alſo are oppoſite, cloſe to the branches; they are five inches long, and two inches and a half broad in the middle, leſſening to both ends, terminating in a point; they are of a lucid green, having ſeveral tranſverſe veins from the midrib to the border; they are entire, and of a thick conſiſtence. The flowers are produced at the ends of the branches, ſitting cloſe to the leaves. When fully blown, the double flower is as large as a middling Roſe. It has a very agreeable odour, on the firſt approach ſomething like that of the Orange flower, but on being more cloſely ſmelt to, like the common double white Narciſſus.

[There are hedges of it in Japan, and the Japoneſe are very fond of it near their houſes, and in the walks of their gardens. Both in Japan and China the fruit is uſed for dyeing yellow [b]. The mucilage preſſed out with the ſeeds produces a fine yellow; that from the ſeeds only is lighter, but tinges water of a lively yellow, and is ſaid ſo dye ſilk of a deep orange, or even ſcarlet, but not the deep China ſcarlet.

It varies with ſingle and double flowers: the former has from five to nine diviſions of the corolla, and ſtamens.—Native of the Cape of Good Hope, Cochinchina, China, Japan, Suratte, Amboina, and the South-ſea iſlands. Introduced about 1754, by Captain Hutchinſon [c], to the Godolphin Indiaman, who found it near the Cape of Good Hope, being attracted by the great fragrancy of the flowers. He preſented it to Richard Warner, Eſq. of Woodford in Eſſex, in whoſe curious garden it continued flowering. [Mr. James Gordon of Mile-end propagated it from cuttings in 1757 [d]. It flowers in july and auguſt.

3. This is a tree, about two fathoms in height, ſmooth, and branching very much. Branches alternate, round, having rings on them from the rudiments of leaves, aſh-coloured, ſmooth, erect, branchletted. Leaves in whorls of three or four, acuminate to both ends, entire, concave, ſomewhat waved, marked with parallel nerves, ſmooth, having hairy glands in the axils of the nerves on the lower ſurface, ſpreading, unequal, longer than the internodes, two inches long and more. Petioles ſhort, gradually widening into the leaf, callous underneath, ſmooth, an inch long. Stipules intrafoliaceous, ſheathing, blunt, membranaceous. Flowers on the branchlets terminating, ſolitary, ſeſſile, erect. Calyx cylindric, widening at top, ſmooth, opening obliquely at top, crowned with from four to ſix petioled, cowled leaflets, villoſe within and moiſtened with honey juice, one-third only of the length of the tube. Corolla white, coriaceous: tube a little incurved, obſcurely ſtreaked, widening a little gradually, very ſmooth: border from ſeven to nine-parted; parts ovate, very blunt, reflex at the edge, quite entire, imbricate, ſpreading very much, villoſe at the mouth, and grooved. Anthers ſeven or eight, but moſt commonly nine: ſometimes the border is ten-parted, with the ſame number of anthers. Germ flat, crowned with rounded, honied tubercles, and ſmooth. Style filiform and ſmooth below, above club-ſhaped, villoſe, longer than the tube of the corolla. Stigma obliquely truncate, grooved. Berry ovate, ſomewhat wrinkled, ſmooth, greeniſh, turning white, one-celled, five-valved, the ſize of a hen's egg, continuing ſeveral years without opening or falling; having a woody hard bark, and ſcarcely any pulp. Seeds lenticular, imbricate, one in each plait [e]. It is not only very clear that this plant is of the genus *Gardenia*, but it reſembles *G. florida* exceedingly in the ſtalk and leaves; the latter are frequently in whorls, and the nerves on the lower ſurface have glands. There is little elſe to ſeparate them but the long funnel-form calyx, appendicled below the tip [f].

Native of the Cape of Good Hope, and introduced in 1773, by Sir James Cockburn, Bart. [g]

4. Native of the Eaſt-Indies: introduced in 1787, by Richard Anthony Saliſbury, Eſq. [h]

5. This reſembles *G. florida* in the ſize and form of the border of the corolla; the tube of the calyx is longer, more filiform, and covered with more ſlender hairs. A gum-reſin very much like Gum Elemi exudes from the cleſts of the bark, and from the leaves. Native of Ceylon. Found there by Koenig [i].

6. The form of the calyx, the contorted corolla, the ſeſſile anthers and their manner of inſertion, the large two-lobed ſtigma, the dry bilocular berry, the diſpoſition of the ſeeds, and the habit of the herbaceous part, all unite to perſuade us that this plant is a true ſpecies or *Gardenia*.

It is ſhrubby, with round branches, rough with hairs. Leaves oppoſite, on very ſhort petioles, an inch in length, and ſmooth. Stipules between the leaves, ſolitary, dilated at the baſe, ſubulate. Flowers axillary, and at the ends of very ſhort branches, ſolitary, ſeſſile. Calyx bell-ſhaped, rough with hairs: the diviſions compreſſed, ſubulate; the ſinuſes rounded. Corolla white: tube elongated, filiform, bent upwards at the baſe, and then becoming ſtraight, rough with hairs; border only half the length of the tube, the ſegments ovate, acuminate, fleſhy. Anthers inſerted above the throat, oblong, upright. Berry oval, with a woody bark. Seeds oval, imbricate, in two rows in each cell.—Native of South-America [k].

7. This is a thornleſs ſhrub, according to Swartz, with oblong-lanceolate leaves, axillary many-flowered peduncles, and ſalver-ſhaped corollas, with a ſhort tube. It differs from the other Gardenias principally in the form of the corolla, which varies much in this genus. Leaves lanceolate, ſinuoſe, veined, quite entire, ſeſſile. Peduncles many-flowered, racemed. Corolla funnel-form, with a ſhort tube, and a five-cleft, equal, ſpreading border. Berry ovate, fleſhy, acuminate at both ends, and as it were

[a] Thunberg. [b] Ibid. [c] Ellis. [d] Hort. kew.
[e] Thunberg. [f] Linn. ſuppl. [g] Hort. kew. [h] Linn. ſuppl. [i] Ibid.

truncate,

truncate, two-celled. Seeds angular, depreſſed, neſtling in the pulp. Native of South America [1].

8. Stem arboreous, erect, branching very much, a fathom and half in height. Branches and branchlets oppoſite, ſomewhat angular, ſtriated, rugged, erect, ferruginous. Leaves oppoſite, on very ſhort petioles, acute, entire, nerved, ſmooth, bright green above, paler beneath, evergreen, having hairy glands in the axils of the nerves on the lower ſurface. Stipules intrafoliaceous, awl-ſhaped, ſhort. Flowers on the branchlets terminating, ſolitary, ſeſſile. Calyx cylindric, obſcurely five-cornered, ſmooth on the outſide, hairy within, one-third of the length of the corolla; ſegments filiform, acute. Corolla ſubcampanulate, yelloviſh-white on the outſide, duſky yellow within, with purple ſpots; ſegments of the border ovate, acuminate, reflex. Anthers ſeldom fix, with a ſix-cleft calyx and corolla. Germ ſlightly convex, unequal, angular, ſmooth. Style filiform, thickening gradually, white, almoſt the length of the corolla. Berry ovate, fleſhy, angular, with about twelve obſcure lines, ſmooth, two-valved, one-celled, pulpy, the ſize of a ſmall pear, black when ripe, opening on one ſide, and falling from the tree when dry; pulp ſoft, like that of the Tamarind [m].

The wood of this is very hard. Flowers white, ſmelling very ſweet, eſpecially during the night. Native of the Cape of Good Hope [n]. Introduced in 1774, by Mr. Francis Maſſon [o].

9. Stem ſhrubby. Branches round, ſmooth, ſpiny, rigid. Spines ſupraaxillary, commonly oppoſite, decuſſated, ſpreading, an inch long. Leaves from buds below the ſpines, ſeveral, ſubſeſſile, ovate, obtuſe, entire, ſmooth, ſpreading, unequal. Stipules minute, briſtle-ſhaped. Flowers axillary, ſolitary. Calyx bell-ſhaped, hirſute on the outſide. Corolla funnel-ſhaped, white. Native of China near Macao [p].

10. This is a very thorny ſhrub, with very ſtiff, round, ſmooth branches. Thorns in pairs, an inch long, ſimple, horizontal, decuſſated, ſtraight, very ſtiff, ſmooth, coming out above the origin of the twigs. Leaves obovate, entire, very ſmooth, oppoſite, a little ſmaller than thoſe of Box. Flowers ſolitary, ſmall, on ſhort pedicels, at the end of each twig. Calyx bell-ſhaped, ſmooth, divided into five ovate, ſpreading ſegments, marked with nerves. Corolla leathery, ſcarcely larger than the calyx, hairy on both ſides, but very much ſo on the outſide; the ſegments of the border rounded or obovate.—Native of the Eaſt Indies, about Madras, in buſhy places. Found by John Gerard Koenig, M.D. Introduced in 1777, by Sir Joſeph Banks, Bart [q].—This is a different plant from *G. ſpinoſa* of Thunberg, which is a native of China, and has the calyx externally, with the corolla very hairy; whereas in this they are ſmooth. See n. 9.

11. Stem ſhrubby. Branches round, villoſe, ſpiny. Branchlets capillary, few, rough with hairs, ſpiny. Spines ſuprafoliaceous, oppoſite, acute, from erect-ſpreading. Leaves from the buds below the ſpines oppoſite, ovate, acute, entire, ſmooth, nerved, ſpreading, on petioles a line in length. Flowers axillary, two or three, the ſize of a grain of rice. Calyx truncate, ſmooth, much ſhorter than the corolla; which is ſubcampanulate, with ovate, acute, reflex ſegments. Style capillary, white, the length of the corolla. Stigma globular. Native of China and the iſland of Ceylon.

12. Stem ſhrubby. Branches round, ſmooth, aſh-coloured, ſpiny, climbing. Spines ſuprafoliaceous, decuſſately oppoſite. Leaves from the buds below the ſpines aggregate, ovate, bluntiſh, entire, ſmooth, ſpreading, unequal, on very ſhort petioles. Stipules briſtle-ſhaped. Flowers axillary, ſolitary. Pedunclés filiform, one-flowered, ſmooth. Calyx ſubcampanulate, ſmooth, one-fourth of the length of the tube of the corolla; ſegments lanceolate, erect. Corolla funnel-form, white, ſmooth; tube cylindric, ſtraight; ſegments of the border lanceolate, ſpreading. Style filiform, the length of the tube. Stigma club-ſhaped. Native of China, near Macao [r]. According to Retzius, it is a ſhrub very much branched both oppoſitely and alternately. Spines ſhort. Leaves oppoſite and ſcattered, ovate, quite entire, the ſame ſize as in *G. dumetorum*. Flowers at the ends of the twigs, uſually ſolitary, pedunclèd, altogether like thoſe of *Jaſminum odoratum*, but the ſtamens and piſtil as in *Gardenia*. It has the calyx of Jaſmin, but more leathery, as is alſo the corolla.

13. A ſhrub with brown ſquariſh branches, the twigs ſhort and growing by pairs, having leaves and two thorns at the end. Leaves elliptic, obtuſe, ſmooth. Corolla thick, leathery, the ſegments rounded, hollow, the tube ſhort. Calyx fleſhy, the five toothlets ſhort, blunt. Native of the Eaſt-Indies in marſhes. Found there by Koenig [s].

14. This is a ſmall tree, about ten feet high, and very ſeldom more than three inches in diameter, frequently branching very near the ground. Branches round, ſmooth, brachiate; the longer ones requiring ſome ſupport; the extreme branchlets are armed with four awl-ſhaped, acuminate, ſtrong, ſpreading, cruciate thorns. Leaves ſubovate, attenuated to both ends, acute, entire, veined, ſometimes wrinkled, ſubhirſute on both ſides, petioled. Flowers ſeſſile, commonly four together from the end of each twig, extremely odorous. Calyx ſmoothiſh, deeply five-cleft; ſegments varying much in form and proportion, but not in number. Corolla white, the tube longer than the ſegments. Stigma ſometimes globular and twin, but more frequently ſplit into two oblong ſegments. Berry not ſtreaked, crowned with a part only of the calyx, at firſt yelloviſh, then brown. Native of South America and the Weſt-India iſlands [t].

15. Spines of the branches decuſſated, leaves roundiſh, teeth of the calyx lanceolate-ſubulate, corolla ſalver-ſhaped. Its affinity to ſeveral of the ſpecies proclaim it to be of this genus. The berry is two-celled, and even when ripe, a very thin partition yet remains. The form of the corolla varies extremely in this genus. The *mitis*, or thornleſs Randia, ſeems to be the ſame, in a more advanced age; when it is common for trees and ſhrubs to loſe their thorns [u].

Browne calls it the Indigo-berry, and ſays that it is a ſmall ſhrub riſing by a branched ſtalk, and ſhooting commonly to the height of ſeven or eight feet; the main ſtem tough and hard, the branches ſomewhat prickly at the ends: the leaves of an oval form, and growing in tufts. The pulp of the berries, which are generally numerous on the ſmaller branches, is very thick, and ſtains paper or linen of a fine fixed blue colour.]

Native of the Weſt-Indies. Introduced before 1733 by William Houſtoun, M.D. who found it near La Vera Cruz, and gave it the name of Randia, in honour of Mr Iſaac Rand, who was a curious botaniſt. It had alſo been diſcovered by Sir Hans Sloane in the iſland of Barbadoes.

PROPAGATION AND CULTURE.

2. The common Gardenia or Cape Jaſmin is eaſily propagated by cuttings during the ſummer ſeaſon, planted in pots, plunged into a moderate hot-bed, covered cloſe with bell or hand-glaſſes, and ſcreened from the ſun. When they have taken root, they ſhould be carefully parted, and put each into a ſeparate ſmall pot, plunging them again into the hot-bed, and ſhading them until they have taken new root, after which they ſhould be gradually inured to the open air. Though the cuttings ſtrike freely, and make ſtrong ſhoots a year or two after, yet in three or four years they are apt to be ſtinted in their growth, the leaves turn pale and ſickly, and the plants frequently die ſoon after.

[The other Gardenias, ſo far as we are yet ac-

[r] Thunberg. [s] Retzius. [t] Jacquin. [u] Swartz.

quainted with them, may be increaſed and treated in the ſame manner. Allowance being made for ſome, which are natives of hotter climates.]

15. The Randia is propagated by ſeeds, ſown early in ſpring, in pots filled with light freſh earth, and plunged into a hot-bed of tanner's bark, obſerving to water the earth frequently but gently. When the plants come up, admit freſh air to them every day when the weather is warm, and refreſh them often with water. In a month's time they will be fit to tranſplant; ſhake them carefully out of the pots, plant each in a ſmall pot filled with light freſh earth, and plunge them into the hot-bed again, ſcreening them from the ſun until they have taken new root; after which they muſt have air and moiſture according to the warmth of the ſeaſon. The plants may remain in the hot bed till towards Michaelmas, when the nights begin to be cold; then they ſhould be removed into the ſtove, and if they are plunged into the bark-bed, it will greatly forward their growth; though they will live in the dry ſtove, in a moderate temperature. During the two firſt ſeaſons, whilſt the plants are young, keep them conſtantly in the ſtove, waſhing their leaves whenever they contract filth: after they have obtained ſtrength, expoſe them in ſummer to the open air for two or three months, in a warm ſituation; but in winter place them in the ſtove, in a moderate warmth.

The leaves continuing green throughout the year, this is a valuable plant for the ſtove.

GARIDELLA. *(So named by Tournefort in honour of Pierre Garidel, M. D. Phyſician at Aix in Provence. Author of Hiſtoire des Plantes qui naiſſent en Provence; 1719, with many figures.)*

Melanthium peregrinum ſ. creticum. *Pona bold.* 46.

DESCRIPTION, *&c.*

This is an annual plant, which riſes with an upright ſtalk a foot high, dividing into ſeveral ſlender branches, having very fine-cut leaves, like thoſe of Fennel, at their joints; the ſtalks are terminated by one ſmall flower, of a pale herbaceous colour.

[Native of the South of France, where it was firſt diſcovered by Monſ. Garidel in 1692. It is found alſo in Italy.

Firſt cultivated here in 1748[a].] It flowers in june and july, and the ſeeds ripen in ſeptember.

PROPAGATION AND CULTURE.

This plant is propagated by ſeeds ſown in autumn on a border of light freſh earth: when the plants come up, weed, and thin them to the diſtance of four or five inches; or if the ſeeds be permitted to ſcatter, the plants will come up without farther care. They do not well bear tranſplanting.

Anonyma pedunculis arcuatis. *Cold. novob.* 98.

Leaves alternate, ovate, entire, ſtem ſhrubby, trailing.

[2. Gaultheria antipoda. *Forſt. fl. auſtr. n.* 196.

Leaves ſcattered, roundiſh, ſerrate-toothed, ſtem ſhrubby, diffuſed.

DESCRIPTION, *&c.*

1. This plant has the appearance of Pyrola or Vaccinium, with a creeping root. It is a ſmall, evergreen, trailing ſhrub, a ſpan high, and ſcarcely branched. Leaves terminating the ſtem, three or four, obovate, ſmooth, coriaceous, ſpreading, with a few acuminate ſerratures. Flowers ſolitary, axillary, pendulous, peduncled. Inner calyx and corolla white[b],] or of an herbaceous colour, and rarely ſucceeded by fruit in England.

[The fruit is red on the outſide and fleſhy, reſembling a berry; the capſule within is very thin, and tubercled with the protuberance of the ſeeds: the partitions alſo within are very thin, and are faſtened to the axis and the furrows of the ſhell: there are five receptacles, which are fleſhy, flatted, bowed, fixed at the baſe, but looſe in the other parts, or connected with the axils of the fruit by a very thin membrane. Seeds very ſmall, ſmooth, ſhining, ferruginous[c].

Native of Canada, on a dry, ſterile, ſandy ſoil. The leaves are uſed there in an infuſion, inſtead of Tea[d].

Cultivated in 1768, by Mr. Miller[e].

2. Native of New Zealand[f].]

PROPA-

PROPAGATION AND CULTURE.

1. The method of preſerving this plant in a garden, is to ſet it in a pot, filled with looſe undunged earth, placing it in the ſhade, and frequenly watering it. Thus the plant may be kept alive two or three years, and bear flowers, but not fruit.

GAURA. (*From* Γαυρος, *ſuperbus.*)

DESCRIPTION, *&c.*

This is a biennial plant. Stem four or five feet high, ſending out ſeveral branches. Leaves oblong, ſmooth, pale-green, ſitting pretty cloſe. Flowers in cloſe tufts at the ends of the branches, pale roſe-coloured; appearing in ſeptember, and when the autumn proves favourable, ripening the ſeeds towards the end of october.

[Gaura agrees with *Spathelia* and *Nitraria* in having the ſhell of the fruit valved at the end. If there be only one ſeed, then it is oblong, and much acuminated; but Linnæus was miſtaken in ſuppoſing this to be the natural number*.]

Native of Virginia and Penſylvania. Introduced in 1762, by Mr. James Gordon†.]

PROPAGATION AND CULTURE.

If the ſeeds are ſown on an open border ſoon after they are ripe, they will more certainly ſucceed than when they are ſown in the ſpring. When the plants come up, keep them clean from weeds, and thin them, if they are too cloſe: tranſplant them in autumn where they are to ſtand, and ſupport the branches to prevent the autumnal winds from breaking them.

Geniſta-Spartium luſitanicum lanuginoſum, aculeis tridentatis longioribus munitum. *Tournef. inſt.* 645.
Spines ternate decuſſated, leaves ſimple lanceolate, ſpikes terminating hirſute.

DESCRIPTIONS, *&c.*

Theſe are Shrubs or Undershrubs, ſome furniſhed with thorns or prickles, but many more ſpecies without them. In moſt of them the leaves are ſimple and lanceolate; but in ſome they are ternate; and one ſpecies is leafleſs. Stipules very ſmall, or ſcarcely any. Flowers both at the ends of the branches and in the axils, ſometimes ſolitary, but more frequently in ſpikes; with a yellow corolla.

1. Leaves obovate, ſomewhat mucronate; but the floral leaves ſubſeſſile, minute. Calyx trifid, the loweſt ſegment three-toothed. Flowers in corymbs, five or ſix together. Legumes white-villoſe. The flowers are ſweet[a].

Native of Spain and the Canaries. Cultivated in 1656, by Mr. John Tradeſcant, junior. It flowers from may to ſeptember[b].]

2. It riſes to the height of ſeven or eight feet, ſending out many ſlender branches, the upper parts of which, for more than a foot in length, ſend out ſmall flowering branches on their ſides, ſupporting

[a] Linn. ſyſt. [b] Ho. t. kew.

five yellow flowers, which appear in june and july: the ſeeds ripen in autumn.

[This reſembles the foregoing ſpecies, but the leaflets are larger, oval, pubeſcent underneath only, ſharp at both ends. The lateral ſhoots are ſhort. Calyxes trifid. Flowers without ſcent. Floral leaves petioled, ſcarcely ſmaller than the others [t].

Legume oblong, narrow, compreſſed, obſcurely ſwelling, brown with a white pile; the valves deeply excavated within, but ſcarcely ſo as to form diſtinct cells. Seeds four or ſix, ſomewhat kidney-ſhaped, black, ſmooth, ſubluciď; with a glandular, prominent, permanent rim, ſhaped like a creſcent, and of a white or yellow colour, round the umbilicus [u].

Native of Spain, Italy, and France. Cultivated in 1748, by Mr. Miller [x].

3. This is a ſmall ſhrub, with branches that are knotty from indentations left by the fallen leaves; the branchlets or ſhoots are leafy, angular, upright, ſilky. Leaves crowded, alternate; leaflets nearly equal, ſharp, rolled back at the edge. Flowers in racemes at the ends of the branches. Calyx three-parted, the loweſt ſegment trifid. Corolla like that of *G. tinctoria*. Legumes villoſe.

Native of the Levant and Spain [y].

4. Native of Spain, Italy, and France. Cultivated in 1748, by Mr. Miller. It flowers from april to june [z].

It is a hardy, evergreen, trailing ſhrub, producing a vaſt profuſion of bloom, which renders it eminently conſpicuous in may and june: it rarely produces ſeed. When tied up properly, and trained to a ſtake, it may vie with moſt of our ornamental ſhrubs [a].]

5. This ſends out ſeveral ſtalks, which ſpread flat on the ground, and divide into many flat branches which are jointed, and their two ſides are edged like a broad-ſword; they are herbaceous but perennial. At each of the joints is placed one ſmall ſeſſile ſpear-ſhaped leaf, ending in a point, of a deep-green colour and ſmooth. The flowers are produced in cloſe ſpikes at the ends of the branches, and are ſucceeded by ſhort hairy pods, which contain three or four kidney-ſhaped ſeeds.

[The ſtalks above the leaves have three wings, under them two. There is one bracte below the pedunclę, and two below the calyx. The banner is flat, rounded and emarginate; the keel in two parts; all the filaments connected; the pollen fulvous; the ſtigma ſomewhat villoſe [t].

According to Haller, the banner is reflex, the wings a little ſhorter than the keel, which is equal in length to the banner: the tenth filament diſtinct from the reſt: legumes black, flatted, containing four ſhining ſeeds, almoſt round: ſometimes five or ſix, according to others.

Native of France, Germany, Switzerland, Savoy, Auſtria, Carniola, Italy, and Spain. I gathered it on Mont Saleve in Savoy. It flowers in june, ſometimes in may, and ripens the ſeeds in ſeptember. Cultivated in 1758, by Mr. Miller [c].

6. Very nearly allied to the foregoing, but all the parts are larger, and the joints of the branches terminate in a lateral leaf, not entire, but three-cuſped. Legumes woolly-white.

Native of Portugal [f].

Neither Miller's n. 6. nor that which he has figured in t. 138. can be this ſort.

7. The roots creep far and wide. Stems many, angular, tough, from a foot to eighteen inches or two feet in height, ſometimes more; branches ſubdivided, ending in ſhort ſpikes of yellow flowers, with ſtipules between them. Leaves alternate, ſeſſile, quite entire, acuminate, an inch long and two lines broad, ſmooth, except that the edges and the nerve underneath are ſlightly villoſe [g]. The five cleſts of the calyx are nearly equal. Standard of the corolla ovate, blunt (emarginate, *Haller*, acuminate, *Scop.*), wings oblong-oval, keel compreſſed: ſtigma a little knob. The loweſt ſtamen longer than the others. Legume ſmooth, almoſt flat, containing ſeveral ſhining ſeeds ſhaped like thoſe of the Lentil [h].

Native of moſt parts of Europe, in paſtures and the borders of fields, particularly in dry gravelly or ſandy ſoils: flowering in july. In the old writers it is called Baſe Broom, Green weed, or Green-wood, Dyer's-weed, and Wood-waxen.

When cows feed on it, their milk, and the butter or cheeſe made from it, are ſaid to be very bitter.

A bright yellow colour may be prepared from the flowers; and for wool that is to be dyed green with woad, the dyers prefer it to all others.

A dram and half of the powdered ſeeds operates as a mild purgative. A decoction of the plant is ſometimes diuretic, and therefore has proved ſerviceable in dropſical caſes. A ſalt prepared from the aſhes is recommended in the ſame diſtemper [e].

8. This reſembles the foregoing, but the ſtalks are neither ſtreaked nor angular; they are ſcarcely marked with lines, nor are the ſtem and leaves at all villoſe. The leaves are ſomething narrower. The flowers are very remote, in a kind of panicled ſpike.

Native of Siberia [i].]

9. This riſes with woody ſtalks two or three feet high, ſending out many taper channelled branches, which grow erect. Leaves ſmall, alternate. Spikes of flowers terminating; ſucceeded by ſhort pods, which turn black when ripe, and contain four or five kidney-ſhaped ſeeds.

[The calyxes as well as the leaves are ſilky and ſhining. *D'Aſſo.*

Native of Spain. Mr. Ray found it near Naples, by the Camaldules.—Cultivated in 1768, by Mr. Miller [t]. It flowers in june and july, and the ſeeds ripen in autumn.

10. This differs from the Common Dyer's weed (n. 7.) in having the branches depreſſed on every ſide and procumbent; whereas that is upright [t].

Root long, running obliquely, and furniſhed with many ſmall fibres. Stem a foot in length or more, much branched, tough; the old branches naked, the young ones cloathed with numerous, minute, oval or oval-lanceolate leaves, entire, ſmooth on the upper ſurface, beneath covered with long white ſilky hairs. Flowers in ſhort ſpikes on the ſummit of the branches, on ſhort hairy pedunclęs. Calyx divided into two nearly equal, acute, hairy, yellowiſh green lips. Corolla except the wings, hairy on the outer ſurface. Legumes hairy [t], containing many ſeeds, ſometimes only two [t]. The legumes are about an inch in length and turn black. To this we may add, that the leaves ſometimes come out two, three, or four together [v].

Native of Sweden, Germany, Auſtria, Carniola, Hungary, Switzerland, France, Italy, and Spain. Not known to grow wild in England till it was diſcovered about Lachford, four or five miles from St. Edmund's Bury in Suffolk, by the late excellent Sir John Cullum, Bart. and Mr. Dickſon. Mr. Woodward obſerves that Cavenham and other heaths near Bury appear yellow with the great plenty of theſe flowers; the flowering branches ſtanding up: at other times it is difficult to find this ſhrub; the ſtem and branches being ſo cloſely procumbent, that they are often found even beneath the moſs. It flowers in may.

11. Native of the Levant [t].

12. Stem much branched: branches tough, without leaves, furniſhed with extremely ſharp ſlender thorns, from a quarter to half an inch in length; the ſhoots of the year grow in bundles on the ſummits of the old ones, and ſparingly from the ſides, bearing numerous, ſmall, bright green, (glaucus on the young ſhoots, *Ray*) oval or lanceolate, (narrower and ſharper on the older branches, *Ray*)

Corollas four-cleft beardless, stalk dichotomous filiform.

48. Gentiana heteroclita.
Lin. syst. 270. *Retch.* 646. *mant.* 560.

Flowers four-cleft irregular, stalk brachiate.

49. Gentiana scandens.
Lour. cochinch. 171.

Stem shrubby climbing, corollas bell-shaped five-cleft, in elongated pendulous panicles.

50. Gentiana fimbriata.
Vahl symb. 3. 46.

Corollas bell-shaped ten-cleft, alternate segments fringed and smaller, leaves lanceolate.

51. Gentiana diffusa.
Vahl symb. 3. 47.

Stem branched dichotomous divaricate, leaves ovate-oblong, peduncles capillary one or two-flowered.

52. Gentiana albens.
Thunb. prodr. cap. 48.

Leaves ovate stem-clasping, calyxes ovate, stem trichotomous.

53. Gentiana dubia.
Thunb. prodr. cap. 48.

Corollas four-cleft, calyx lanceolate, panicle terminating trichotomous superdecompound.

DESCRIPTIONS, &c.

The numerous species of this genus have very few characters in common; some of them indeed differ so much from others, that they have been ranged under separate genera, and some are yet of opinion that the genus should be divided. They are all herbaceous plants; the Gentians properly so called are perennial, most of the Gentianellas and the Centorys are annual. The leaves are simple, ovate, lanceolate or linear, or between these figures, opposite on the stem, and entire; commonly marked with five or three strong nerves. Flowers either axillary or terminating, solitary or else in bunches or whorls. Anthers coalescing in several of the species; as in Syngenesia Monogamia. Few of the species are commonly known or cultivated. Many of the Gentianellas though small are eminently beautiful, and a great ornament to the alpine regions.

1. See Exacum viscosum.]

2. Root thick, of a yellowish brown colour, and very bitter taste. Lower leaves petioled, oblong-ovate, a little pointed, stiff, yellowish green, having five large veins on the back, and plaited. Stem three or four feet high and more, with a pair of leaves at each joint, sessile or almost embracing, of the same form with the lower ones, but diminishing gradually to the top. Flowers in whorls at the upper joints.

[Peduncles upright, one-flowered. When the flower opens, the calyx bursts on the side. Segments of the corolla from five to eight, with frequent dots scattered over them, divided almost to the bottom. At the base of the germ as many green tubercles as there are segments in the corolla. Filaments reaching beyond the flower. Anthers very large. Fruit short, swelling in the middle. Seeds often barren [b].

Native of Lapland, Sweden, Germany, Switzerland, France, Italy, and North America.

Haller observes that it occupies large tracts of country, untouched by any cattle. I observed this very remarkably about Chaud de Fond, and in other parts of Switzerland. It flowers in june and july.

Our old authors call it Felwort and Bitterwort. Before Hops had established their reputation, this with many other bitter herbs was occasionally used in brewing. Mr. Houghton (at the end of the last century) affirms, that he has divers times sold it for that purpose [c].

The root of this species of Gentian, imported from Switzerland, Germany, &c. is the principal bitter now employed in medicine, though the roots of several other sorts are said to be equally efficacious, and are even preferred by some. As the intense bitters are generally admitted to be not only tonic and stomachic, but also anthelmintic, antiseptic, emmenagogue, antiarthritic, and febrifuge, this root has

[b] Haller. [c] Collections, 2. 335.

a better claim to the poſſeſſion of theſe powers than moſt of the kind.

Many dyſpeptic complaints, though ariſing from the debility of the ſtomach, are more effectually relieved by theſe bitters than by Peruvian bark: and Gentian joined with equal parts of tormentil or galls, has conſtantly ſucceeded, as we are told by Dr. Cullen, in curing intermittents, if given in ſufficient quantity.

As a ſimple bitter, Gentian is rendered more grateful to the ſtomach by the addition of an aromatic, and for this purpoſe orange-peel is commonly uſed [d].

Gerarde informs us, that "maſter *Iſaac de Laune*, a learned phiſition, ſent him plants of this for the encreaſe of his garden from Burgundie: and that it is named in Engliſh Felwoort Gentian, Bitterwoort, Baldmoyne, and Baldmoney."

3. Root even larger than in the foregoing ſort; as thick as a man's arm and two feet long, white within and ſtriated on the outſide, extremely bitter, and uſed medicinally in ſome countries, inſtead of *G. lutea*, with equal ſucceſs. Stem ſmaller, a foot or eighteen inches in height. Leaves ſomewhat broader. Calyx ſpathaceous, obtuſe, by which it is diſtinguiſhed from the ſixth, in which the calyx is ſix-cleft. Corolla ſmaller, divided into five or ſix ſegments, ſometimes ſeven, duſky or pale purple, with the dots running into lines [e]. Haller is of opinion that it can ſcarcely be ſeparated from the ſixth ſpecies.

Native of Denmark, Switzerland, and Sileſia.—Introduced in 1768, by Profeſſor de Sauſſure [f].

4. Root creeping with a tranſverſe ſtock, and abundance of whitiſh fibres. Root-leaves often a ſpan in length, ſtanding up above the ſtem, broad-lanceolate, five-nerved, ſheathing at the baſe. Flowering-ſtem coming out on the ſide of theſe, procumbent at bottom but gradually riſing, having only one or two pairs of leaves, beſides the floral ones on the top. Flowers ſeſſile in aggregate whorls at two ſeparate pairs of leaves. Calyx ſmall, membranaceous, unequally four-toothed. Corolla ſmall, of a livid pale colour, the border pale blue, four or five-cleft, the ſegments very ſhort and ſharpiſh. In its habit this is between the *purpurea* and *cruciata*, as *decumbens* and *algida* are between this and *Pneumonanthe*. The herbaceous part is hardly bitter.

Native of all Siberia, eſpecially the eaſtern part, where the *cruciata* is not found flowering in july and auguſt [g].

5. Root yellow on the outſide, very bitter, fuſiform, branched. Leaves and even bractes approaching in form to thoſe of *G. pannonica* (n° 7.), ſoft, thickiſh, ovate-lanceolate, running into a longer point than in *G. punctata*; prominent nerves on the lower ſurface five or ſeven. Stem ſmooth and even, from dark blue becoming green, erect, two ſpans in height, round but alternately ſomewhat ancipital between the joints. Flowers almoſt ſeſſile in two or three whorls, in each axil from one to three. Calyx in ſhape of a ſhort bell or rather baſin, ſeven-cornered, membranaceous, whitiſh, except at the corners, where it is ſky-blue; border gaping, ſeven-cleft; toothlets ſhort, broadiſh, blunt, entire, flat, green, leafy. Corolla large, ſulphur-coloured, ſhining as if poliſhed, ſtreaked longitudinally, but not ſpotted, bell-ſhaped, bellying out and almoſt ſpheroidical at the baſe, and thence cylindric; border ſeven-cleft; clefts equal, erect, contiguous, obtuſely triangular, quite entire.

Native of Carinthia, on mount Garten in Reichenau; flowering in july. Diſcovered originally by Burſer [h].

6. This agrees in many reſpects with *G. pannonica*, but the leaves are more ovate, leſs elongated, and more ſtrict; the calyxes ſhallower and more in form of a baſin, the calycine teeth much narrower, ſharper, and leſs leafy; the corolla of a papery ſubſtance, extremely thin, of a dull and very pale greeniſh ſtraw-colour, with very minute dots thickly and irregularly ſcattered over it. Segments of the border commonly ſeven, ſometimes eight, but very ſeldom ſix, always ſhorter, narrower, contiguous, rounded, blunt, without any auricles at the baſe; and finally the bellying of the corolla is blunter and almoſt the ſame over the whole bell [i].

Native of Auſtria, Sileſia, Italy, &c. Introduced in 1775, by Drs. Pitcairn and Fothergill [k].

7. Root yellowiſh on the outſide, whitiſh within, intenſely bitter. The whole plant is ſmooth and ſhining. Stem from half a foot to two feet in height, round or ſlightly angular, erect, as finger thick at the baſe, which is covered with ſheathing ſcales, having a bifid or trifid mouth. Leaves oppoſite, broad ovate or lanceolate, acute, quite entire, bright green, ſomewhat plaited, having five prominent pale nerves on the back, attenuated into connate petioles; the upper ones more ſeſſile. Flowers from the axils on very ſhort peduncles, three, four, or five, ſeldom more on each ſide, forming whorls, ſupported by bractes reſembling the leaves. There are commonly two or three whorls, with flowers much more numerous in the upper one; but in ſmaller plants there is only one. Calyx bell-ſhaped, looſe, thin, obſcurely ſix-cornered, divided to the middle into the ſame number of ſegments with the corolla, theſe are lanceolate, acute, ſpreading, and two of them oppoſite to each other larger and diſtant. Corolla large and elegant, divided into ſix or ſeven, roundiſh, very blunt, erect ſegments; the outſide at the baſe and the whole inſide of the tube are pale yellow, the reſt is dark purple; the whole ſprinkled with very dark purple dots [l].

Although this reſemble *G. purpurea*, yet it has a much ſmaller flower, of a different colour from that; the ſtem-leaves alſo are ovate and ſharpiſh, but never produced into a point [m].

Native of Switzerland, the Tyrol, Sileſia, and the Carpathian mountains.

8. Stem a foot or eighteen inches in height, having the air of *G. aſclepiadea*, round, ſmooth, quite ſimple. Leaves ſpreading, five-nerved. Flowers from the upper axils uſually two together, and three at the top of the ſtalk, crowded together into a corymb, on ſhort peduncles, the ſame ſize as in the next ſpecies, the upper one flowering firſt. Calyx ſmall, angular, truncate, with linear ſegments from the angles. Corolla bellying, naked within, contracted in the tube, blue, the border divided into five, ſix, or ſeven reflex ſegments, dotted at the baſe, having upright ſtraps cut into ſeveral capillary jags between each ſegment. The number of ſtamens correſponds with the number of ſegments in the corolla. The whole plant is ſmooth. Both root and herb are very bitter.

Native of the mountains of Perſia near the Caſpian ſea, and of the Cherſoneſus Taurica [n].]

9. Stem upright, near a foot high. Leaves ſmooth, about two inches long, and three quarters of an inch broad at the baſe, embracing there, and ending in an acute point; they are of a fine green, have five longitudinal veins, joining at both ends, but diverging in the middle, and diminiſh in ſize as they are nearer the top. Flowers in pairs oppoſite, on ſhort peduncles; they are pretty large, bell-ſhaped, and of a fine blue colour.

[Leaves bluntly ſerrate, reſembling thoſe of *Aſclepias*, whence it has the trivial name. Calyx obſcurely pentangular, ſcarcely the third part of the length of the corolla. Stamens much ſhorter than the corolla, with long, yellow anthers. Like ſeveral other ſpecies, it varies with a white corolla [o].

It differs from the foregoing principally in ſize, in having flowers in the axils to the middle of the ſtalk, a ſimple corolla, thrice five-cleft not dotted. The lower leaves five-nerved, the upper three-nerved. Calyx ſomewhat ſpathaceous, putting out ſegments often as long as the corolla. This is the

[a] Woodville. [b] Hallet and Krocker. [c] Hort. kew.
[d] Pallas. [e] Jacquin.
[f] Jacquin. [g] Hort. kew. [h] Jacquin. [i] Linn. ſyſt.
[k] Pallas. [l] Haller and Krocker.

moſt taſteleſs and leaſt bitter of the genus [a].—Ray ſays that the root is very bitter. Haller affirms that the tube of the corolla is ſpotted, and that ſometimes the ſegments are ſo. According to Linnæus the calyx is as long as the corolla.

Native of Switzerland, Hungary, Stiria, Auſtria, Sileſia, Piedmont, Barbary, mount Caucaſus, &c. It flowers with us in july and auguſt. Cultivated in 1629, as appears from Parkinſon [b].

10. Root fibrous. Root-leaves none. Stem upright, very ſtraight, a ſpan high, round, furniſhed with very ſmall leaves at bottom, becoming gradually longer higher up, decuſſately oppoſite; they are ſtiff and ſomewhat rigid, blunt at the end, and turned back at the edge; the largeſt are near three inches in length. Flowers at the end of the ſtalk in threes, and ſometimes another pair of them from the next axil of the leaves. Calyx purpliſh, unequally five-cleft, ſubſpathaceous, cut more deeply on one ſide, the ſegments linear and ſharp, alternately larger and ſmaller. Tube of the corolla angular, whitiſh; the border dark blue, with ſubcordate blunt ſegments, diſtant at the baſe from each other with a right-lined interval. Filaments unequal; anthers upright. Germ fuſiform with a bifid ſtigma. It is really different from *G. Pneumonanthe*, with which it may eaſily be confounded, from having a flower of the ſame colour, by its being ſo ſtiffly upright and bitter. It flowers in july and auguſt.

Native of Eaſtern Siberia [c].]

11. Stem upright, about a foot high. Leaves ſmooth, an inch and half long, and leſs than a quarter of an inch broad; they have no petioles. Flowers on the top of the ſtalk, three or four in number, on peduncles alternately above each other; they are large, and being of a deep blue colour, make a fine appearance.

[Stem ſeldom or ever branched, round or very obſcurely angular, ſmooth as is the whole plant. Leaves vary from linear to almoſt ſpatulate [d].

Haller ſays that ſome are elliptic and obtuſe, others linear and acute—Scopoli, that they are not truly linear but linear-lanceolate—Pollich, that they are linear and bluntiſh—Krocker, that they are either lanceolate-linear or completely linear. The flowers according to *Haller* are ſolitary and almoſt ſeſſile in the axils or boſoms of the leaves. Pollich ſays, that one terminates the ſtem, and the reſt are axillary, ſolitary and ſubſeſſile—Scopoli, that the lower corollas are peduncled and from the axils. Krocker deſcribes them as terminating and axillary, peduncled, ſolitary or in pairs, ſix, eight, or ten in the whole, with two or four ſtipules under the peduncles. Theſe variations occur in different ſoils and ſituations: with us certainly the plant ſeldom bears more than one or two flowers; but after a wet ſpring it is found much more luxuriant, bearing, five, ſix, or ſeven flowers [e].

Calyx cylindric, or very obſcurely angular, with linear leaflets often reflex at top, ſcarcely a third of the length of the corolla: which is plaited in angles, of different ſhades of blue, the tube paler and dotted within. Anthers connected full as much as in *Lobelia*, and much more ſo than in *Viola* [f]. Five glands at the baſe of the germ, as in *G. lutea* [g]. Stigma revolute, remarkably long [h]. It has the bitterneſs and qualities of ſeveral among its congeners [i].

Pallas diſtinguiſhes this from his *triflora*, by its having a more ſlender ſtalk, and leaves more lanceolate and acute. One flower at the end, the reſt axillary, all peduncled, when there are ſeveral; for ſometimes there is no more than one. Calyx deeply five-cleft, the ſegments linear, two alternate ones larger than the reſt. Corolla larger, more dilated at the throat, plaited, the ſegments ſharper and ſubſerrate, with a tooth of the plait between each; the ſtructure of the flower therefore is very different from the foregoing.

Native of Sweden, Denmark, England, Switzerland, Carniola, the Palatinate, Sileſia, Piedmont, in the temperate parts of Ruſſia and all Siberia, in moiſt meadows and marſhes: Ray found it near Lindau in Germany. It flowers in auguſt and ſeptember; or, as Linnæus obſerves, with the Colchicum. With us it is not very common in the ſouth, but in the north much more ſo. In Lincolnſhire and Yorkſhire abundant, in the boggy parts of heaths, as in Tatterſhal-park [k]. Found by Mr. Newton between Clapham and Engleton. Near Doncaſter by Mr. Tofield. Near Milthorp in Weſtmorland, and in Lancaſhire common. Near Tunbridge in Kent, by Dr. Wilmer [l]. On Longfield downs near Gravesend, near Greenhithe, Cobham, &c. in Kent, and near Bath, by Gerarde. At Lellingſtone, and near Dartford in Kent, and in the weſt country in divers places, by Parkinſon. Johnſon (Ger. emac.) is of opinion that Gerarde did not know the plant, and ſays that he never found it but once, and that was on a wet mooriſh ground in Lincolnſhire, called Netlecommoor, two or three miles on this ſide Caller. Johnſon was ſo well acquainted with Kent, that he cannot well be miſtaken. On Stratton Strawleſs heath near Norwich, by Stillingfleet.

12. This riſes uſually ſixteen inches high, with upright ſtraight ſtems, having long ſharp-pointed oppoſite leaves, ſpreading horizontally. From the axils of theſe come out four or five blue flowers [m].

Native of North America. Introduced in 1776, by Mr. William Young. It flowers in auguſt and ſeptember [n].

13. Leaves oblong, acuminate, ſlightly villoſe. Flowers bell-ſhaped, ventricoſe, erect, pale yellow or white on the outſide [o], and variegated with lines on the inſide.

Native of Virginia [p].

14. Root large, woody, branched. A ſet of ovate-lanceolate leaves ſpreads on the ſurface. Stem from one to three inches in height, with one or two pairs of leaves on it, and terminated by one very large, upright, handſome flower (in a garden, when the plants are ſtrong, there are ſometimes more). Calyx angular, cloven half way down; the ſegments lanceolate, acuminate, ſcarcely a third part of the length of the corolla; which is of a deep azure blue, dotted on the inſide. Five melliferous tubercles at the baſe of the germ, as in *G. lutea* [q].

This plant, in its natural alpine ſituation, has little or no ſtem, whence its trivial name; but it acquires one in a ſtate of cultivation.

Native of Switzerland, Auſtria, Carniola, Sileſia. Ray remarked it on the higheſt parts of mount Jura. It flowers in our gardens in april and may; and ſometimes a ſecond time in the autumn. In the alps the time of flowering is june, july, and auguſt. It was cultivated in 1629, according to Parkinſon. In 1636, it was to be found in moſt of our choice gardens, as with Mr. Parkinſon, Mr. Tradeſcant, Mr. Tuggye, &c. [r].

15. Root ſmall, annual, very ſlender, bitteriſh. Stems in tufts, from an inch to a ſpan in height, ſeldom branched, decumbent at bottom then upright, jointed, leafy, terminated by one flower. Root-leaves four, ſeldom more, ſpreading on the ground; both they and the ſtem-leaves ſmooth, quite entire, bright green, ſeſſile, flat. Calyx cloven to the baſe, green, ſmooth, the ſegments equal, lanceolate. Corolla deep blue, at the baſe and throat whitiſh. It flowers at the end of auguſt [s].

Native of Dauphiné, Savoy, Piedmont, Sileſia. Diſtinguiſhed from *G. nivalis*, to which it is very nearly allied, by its tender ovate leaves without veins, its ſlender ſtalks bearing uſually one flower only, the ſegments of the flower nearly erect, and the calyx by no means long, and tubular [t].]

[a] Pallas. [b] Hort. kew. [c] Pallas. [d] Engl. bot. [e] Sutton in Engl. bot. [f] Engl. bot. [g] Haller. [h] Krocker. [i] Haller.

[k] Ray. [l] Hudſon. [m] Catesby. [n] Hort. kew. [o] Gronovius. [p] Linn. [q] Haller and Krocker. [r] Ger. emac. [s] Krocker. [t] Allioni.

16. This

16. This rises with an upright branching ſtalk, near two feet high. Leaves oblong, ſmooth, acute-pointed. The upper part of the ſtalk divides into ſeveral forks, between which are ſix or ſeven long naked peduncles, each ſuſtaining one large blue flower.

Native of the Weſt Indies, diſcovered by Plumier; and found afterwards by Houſtoun plentifully at La Vera Cruz, in low moiſt places, where the water ſtagnates, remote from the coaſt. Cultivated by Mr. Miller before 1733.

17. Root perennial. Root leaves ten or more, in a bunch, linear-lanceolate, three-nerved. Stems one or two, coming out on the ſide of the bunch of leaves, decumbent at bottom then riſing, a ſpan or a foot in height, naked at bottom, a pair of leaves in the middle, bearing leaves and flowers at the end. Stem leaves linear. Flowers ſeſſile, commonly three terminating among the top leaves, and two pairs oppoſite accompanied alſo with leaves; ſeldom in threes. Calyx angular, ſmaller than in *G. Pneumonanthe*, with the ſegments narrower, awl-ſhaped, but alternately larger, as in that. Colour, figure, and almoſt the ſize of the corolla, as in *G. Pneumonanthe*. Filaments only half the length of the corolla. Germ fuſiform. Stigma ſharp.—Sometimes the plant is larger, and then the root-leaves are near an inch in breadth, the flowers more in number; and ſometimes there is a little axillary branch with one flower on it, at the loweſt pair of ſeſſile flowers.

In farther Siberia; flowering from july till ſtopped by the froſt. It is gently bitter and aromatic: hence it is uſed medicinally in Tibet.—It varies with a white and purpliſh white corolla [n].

18. Root perennial. Stem very ſtraight, round, from a finger's length to a ſpan in height, with two or three pairs of broad-lanceolate three-nerved leaves on it, ſlightly ſheathing it at the baſe. Flowers three or four together ſeſſile among the upper leaves, with ſometimes an acceſſory one or two from the next axil. Calyx purpliſh, cylindric, cut on one ſide when the flower is in maturity, cloven half way down, the ſegments linear, two alternately larger than the reſt. Corollas large, plaited, of a milky colour and diaphanous, with ſtreaks in five rows converging by pairs like flames, dots in rows on the tube, and very ſmall dots more frequent towards the border, of a livid blue colour, more or leſs deep: the ſegments of the border ſhallow, triangular and diſtant. Filaments thickeſt in the middle, blue: anthers upright, lemon-coloured. Germ fuſiform, with a ſlightly bifid ſtigma. Capſule included in the withered corolla. Seeds gray, ſcarioſe and wrinkled. The leaves next the root are collected into a bunch; they are pale green, juicy, tender, and linear-lanceolate. The whole plant becomes pale in drying. It reſembles the foregoing ſpecies, and is very nearly allied to it, but differs in ſome eſſential characters; Gmelin therefore makes it a variety of *G. Pneumonanthe*, and Linneus of *G. puſtata*, without reaſon.

On the ſnowy alpine tops of eaſtern Siberia, and other parts of the Ruſſian empire; flowering in auguſt.—Intenſely bitter, and proper to be uſed medicinally [o].

19. Stem herbaceous, ſingle, very ſeldom ſubdichotomous, ſlender, round, grooved, erect, ſmooth and even, a hand or a ſpan in height. Leaves nerveleſs, ſomewhat fleſhy, very ſmooth, quite entire, oppoſite, at the peduncles frequently in fours, ſpreading, yellowiſh green, two inches long: root-leaves approximating, on ſubimbricate channelled petioles. Peduncles two or three together, ſeldom four, from the top of the ſtem, one-flowered, angular, from upright ſpreading, two inches long. Flowers white, upright.

Native of New Zealand. Found in Duſky-bay, march 7th, 1773.

[n] Pallas. [o] Ibid.

20. Native of New Zealand [p]. Found alſo in Duſky-bay.

21. Root filiform, ſlender, woody. Root-leaves in a ring, thickiſh, with nerves ſcarcely viſible. Stem ſimple, round, upright, from two to four inches in height, having three or four pairs of ſeſſile leaves on it, which are ſomewhat fleſhy, and ſmaller than the root-leaves. Flowers uſually three, ſeldom only one at the end, together with an acceſſory pair from the uppermoſt axils. Calyx blueiſh, ſmall, bell-ſhaped, the ſegments awl-ſhaped, and equal. Corolla three times as long as the calyx, ſomewhat bellying, pale blue with the tube whitiſh; the ſegments of the border blunt. Anthers white. Capſule fuſiform, wrapped in the corolla.

There is a variety of this, in high, expoſed, rocky ſituations, with two or three flowers ſitting cloſe to the root-leaves, without any ſtalk.

The former is native of the higheſt mountains of Kamtſchatka; flowering from june to auguſt, and ripening its ſeeds in ſeptember [q].

22. This is a little plant hardly two inches high. A perennial yellow branched root puts up ſeveral ſimple ſtalks, each ſupporting one flower. Root-leaves ſpread in a ring, ſmooth, ovate-lanceolate; on the ſtalk two or three pairs. Calyx five-cornered, half the length of the corolla. Segments of the corolla ſlightly ſerrate, either blue or beautiful deep azure, and between each a ſmall horned whitiſh blue proceſs. Capſule fuſiform, long, burſting when touched [r].

It differs from *G. pumila* in the leaves being channelled, more rigid, and half-ſtem-claſping; the plaits of the calyx, terminating it in ſo many teeth, elevated; the little ears or proceſſes emarginate; the ſtigmas finely ſerrate and reſembling a little drinking glaſs [s].

In Linn. ſyſt. it is obſerved that it is nearer to *Primula*, and ſcarcely bitter.

Native of Switzerland, Savoy, Piedmont, Auſtria, Carniola, Sileſia; flowering early in the ſpring; both in moiſt meadows and in alpine ſituations. Ray found it abundantly on the mountains near Geneva; and I gathered it in flower on mont Saleve the 13th of april, 1779. On the high Alps it flowers later.—Teeſdale foreſt, Durham; and between Gort and Galloway, Ireland.

It varies with a white flower. A beautiful blue colour may be extracted from the flowers as they are more commonly found [t].

23. Perennial. This is very like the foregoing, but the corolla is regularly ten-cleft, the ſegments blunt, the alternate or outer ones green on the outſide, within all are blue. Leaves linear or linear-lanceolate. Stalk perennial, procumbent, with upright branches, bearing one flower the length of the branch.—Native of the Pyrenees [u].

24. Root ſlender, two or three inches long. Both root-leaves and ſtem-leaves cloſely imbricate, ſubulate-linear, ſharp. Stem uſually ſingle, but ſometimes two or three, about an inch in length, ſomewhat naked under the flower, with one pair of leaves near it. Calyx angular, the ſegments equal, ſharp, and diſtant at the baſe. Corolla three times longer than the calyx, above two inches in length, of a very deep blue colour, with pale flame-like ſtreaks riſing from the tube. Anthers upright, ſagittate, yellow. Germ fuſiform-club-ſhaped, with the ſtyle produced, and a fungous ſimple ſtigma. Capſule lanceolate, wrapped in the decayed flower. Seeds grayiſh-brown. It varies ſometimes with a four-cleft or ſix-cleft corolla.

It is very nearly allied to *G pyrenaica*, and like that is almoſt void of bitterneſs: it may therefore only be a variety ariſing from ſituation. The principal difference conſiſts in the ſuperior ſize of the flower, the ſtrength of the whole plant, and the ſhortneſs of the ſtalk.—*G. pumila* of Linneus and Jacquin, ſeems to be the ſame plant with *the pyrenaica*.

[p] For ſee [q] Pallas. [r] Haller. [s] Haller, Crocker. [t] Linn. mant.

Native

Native of the ſnowy cliffs of the Altaic alps [a].

25. Stems one-flowered. Corolla ſcarcely ſerrate [b]. Leaves ſharp, ſcarcely four lines long, and one broad. Stem about an inch in height, with two pairs of leaves, one near the calyx, which is cloven half way down, and is angular with five raiſed lines. Tube of the corolla yelloviſh, not plaited; ſegments quite entire, with horned proceſſes [c].

Haller is of opinion that this does not differ from *G. verna*: and Pallas cannot ſee any difference between the ſpecimens which he received of this from Jacquin, and the *pyrenaica*.

According to Villars, it differs little from *verna*, but it is ſmaller and has linear leaves; the ſtems have more leaves on them, namely three or four pairs, and are creeping, the diviſions of the corolla are obtuſe and are very finely toothed.

Native of the mountains of Dauphiné, Auſtria, and Carniola.

26. Leaves blunt, not ſharp, as in *G. verna*, [a]. Root-leaves ſpreading in a ring, perfectly round. Stem often proſtrate, three inches or more in height, with eight or ten pairs of ovate leaves on many. Flower ſolitary, large: calyx half the length of the tube of the corolla, divided not more than a third of the way down into five ſharp ſegments, frequently violet-coloured. Tube of the corolla long: ſegments ovate, moderately acuminate, a little ſerrate, of the fineſt ſky blue: proceſſes ſhortly horned ariſe from a white line of the tube. It varies with a white flower, like moſt of the others [a].

The Siberian plant is taller, and larger in all the parts than the German. Root filiform, ſimple, or branching only into fibres. Root-leaves ſeſſile, ovate and ſharp. Stem naked, a finger's length, ſometimes a long ſpan high, with one pair of leaves only towards the flower, and two floral leaves. Calyx divided into five equal, ſharp ſegments. Border of the corolla ſpreading, equally five-cleft; ſegments ovate-oblong, deep blue, very finely ſerrate. Hence *G. verna*, from Switzerland, with both bluntiſh and ſharp leaves, does not differ from *G. bavarica*. Theſe therefore make one ſpecies as *G. pumila, pyrenaica*, and perhaps *altaica* do another. But *G. iſlandica* of *Flor. dan. t.* 317. differs widely from *G. bavarica* [b].

Native of Switzerland and Germany. About the lake Baikal, and on the Carpathian mountains in the Ruſſian empire: flowering early in the ſpring.

It was introduced in *1775*, by the doctors Pitcairn and Fothergill [c].

27. Root annual. Stem erect, a ſpan high. Branches at the root ſeveral, ſmall, very upright. Root-leaves ovate, ſmooth, ſmall; ſtem-leaves ſimilar, larger, ſeſſile, bluntiſh. Flowers terminating, few, in a head. Calyxes narrow, ſubpeduncled, divided into five awl-ſhaped ſegments. Tube of the corolla the length of the calyx: border yellow, the ſegments quite entire, without any teeth interpoſed [a].

Retzius thinks that *G. involucrata* of Friis (act. Haffn. x. t. 1. f. 2.) and the Flora Danica (t. 344.) may be referred to this ſpecies. It is entirely different from *G. quinqueflora*, n. 38.

Native of the mountains about Bourdeaux, and of Norwegian Lapland.

28. Root annual, ſmall. Stem ſometimes one-flowered, but frequently branched, having one flower coming out from each axil regularly one above another, often alternately, but ſometimes in pairs. Root-leaves ovate, bluntly lanceolate, few: ſtem-leaves a little longer, ovate, acuminate, as far as eight pairs. Calyx five-cornered, half the length of the corolla, cut one-third of the way; ſegments ending in a long and very ſharp point. Corolla ſomewhat ſtiffer than the other Gentianellas. Segments lanceolate, greeniſh on the outſide, deep blue within, having a tinge of green. Proceſſes between the ſegments ariſing from the white lines of the tube.

[a] Pallas. [b] Linn. ſyſt. [c] Scopoli. [d] Linn.
[e] Haller. [f] Pallas. [g] Hort. kew.
[h] Linn. ſpec.

In the mountains of Lapland; in the Alps of Switzerland, where as Haller obſerves it is a genuine alpine plant; and between Savoy and Piedmont, as Mont Cenis, &c. and on the Pyrenees, adorning them, as Linneus ſpeaks, with the ſplendour of its deep vivid blue flowers. It has alſo been found by Mr. Dickſon on Ben Lawers in Scotland.

It varies like moſt of the others with a white corolla. The fading from blue to white is indeed very common in flowers.

29. Root annual, filiform, ſomewhat branched, white. Root-leaves ſpreading in a ring, very much crowded together, ovate-rounded. Stem-leaves imbricate, ovate-ſharpiſh, decuſſated. Stems from two to twenty, uſually ſimple, but ſometimes branched dichotomouſly, in the flowering plant very ſhort, but in the fruiting plant lengthened out, the leaves becoming more remote and produced into an oblong form. Flowers ſmall. Calyx largiſh, five-cornered; the ſegments awl-ſhaped, ſharp, equal. Corolla angular and plaited, pale azure on the outſide with green ribs, the ſegments acuminate with ſmaller teeth interpoſed. Capſule involved in the flower, the corolla becoming green; it is ſhaped like a long club, and compreſſed: when ripe, the valves are turned back a little, and the minute, yelloviſh ſeeds are thrown out. It varies with a white corolla.—It approaches very near to *G. nivalis*; and is larger in cold ſituations, than in more ſouthern ones. Being very bitter, it is uſed medicinally in Dauria. It flowers in the middle of may: and is found from the river Jeniſea to the eaſtern ocean in ſandy wet meadows, and eſpecially by lakes and rivers [a]. It is found alſo in China and Japan.

30. Root ſlender, fuſiform, fibrous, yellow, annual (perennial, *Allioni*). Root-leaves ſpreading on the ground in a four-cornered tuft, but ſoon decaying. Stem upright, a finger's length or a hand in height, ſometimes higher, ſlightly angular, ſmooth; branches oppoſite, each with the ſtem terminated by one flower. Leaves ſeven pairs or more, ovate, blunt, quite entire, connate-ſeſſile, upright, bright green, ſmooth. Calyx five-cornered. Corolla eight lines in diameter, greeniſh on the outſide, fine ſky-blue or azure within; ſegments lanceolate, ſpreading, with horned, ſmaller whitiſh ſegments interpoſed. The corolla is ſometimes ſix-cleft [a].

Ray remarks, that this ſpecies differs from all the Gentianellas which he has obſerved, in having the tube of the corolla no longer than the calyx, but the ſegments of the former ſpreading immediately over the top of the latter, as in the Pink.

Stigmas whitiſh, forming a cap flatted at top, with glands all round [a]. Capſule almoſt cylindric, long; filled with abundance of ovate, acuminate, wrinkled ſeeds [a].]

Mr. Miller obſerves, that after the top flower decays, there are frequently two ſmaller flowers come out from the ſide of the ſtalk, at the two upper joints; theſe flowering after each other, there is a ſucceſſion of flowers till autumn.

[Native of the mountains of Switzerland, Germany, Auſtria, Idria, and Italy; flowering in june. Ray relates that he found it abundantly in going from Munich to Augſbourg.

This alſo varies with a white flower.

31. The whole plant is only about a finger's length. Stem ſimple, ſlender, upright, angular. Leaves ſmall, roundiſh, broad, veined, connate, two or thee pairs. Flowers terminating, in a looſe, broad, ventricoſe, membranaceous, ſtriated calyx; ſegments of the corolla oblong, narrow equal, yellow.—Native of the Cape of Good Hope [a].

It ſeems to belong to a different genus.

32. The whole plant ſmooth and glaucous. *Root* fibrous [a], annual, woody, yelloviſh. *Stalk* from four inches to a foot in height [a], upright, hexangular [a],

[a] Pallas. [b] Pollich, Haller. [c] Scopoli.
[d] Haller. [e] Burman. [f] Lyons Mſs.
[g] Stokes in With. [h] Lyons Mſs.

or quadrangular, generally ſimple, but frequently putting out upright ſimple branches ſome way above the root, and ſometimes branching all the way to the top. *Leaves* next the root oblong, or wedge-ſhaped, narrowed at the baſe, blunt at the end—ſtem-leaves lanceolate, pointed, upright, the uppermoſt often bent inward: floral leaves linear:—all ſeſſile, three-nerved, quite entire. *Flowers* in a corymb, upright, and ſubſeſſile: *calyx* upright, ſlightly adhering to the tube of the corolla, permanent; ſegments awl-ſhaped, connected by a membrane; at the baſe, two very ſhort awl-ſhaped bractes[a]: *corolla*, tube one-third longer than the calyx, ſlightly coloured, ſtreaked; border generally roſe-coloured or pink, plaited at the baſe, the ſiſſures keeled on the outſide, and the ſegments on the inſide[b]; there are no ears or proceſſes between the ſegments[c]. *Filaments* from the top of the tube, ſhorter than the corolla: *anthers* oblong, upright after they have ſhed their duſt twiſted ſpirally from right to left; which circumſtance has induced ſome botaniſts to remove this plant into the genus *Chironia*. *Germ* oblong, filling the tube of the corolla, having a longitudinal furrow on each ſide: *ſtyle* one, half the length of the germ, inclining to one ſide, cloven half way down, and diviſible without much force all the way: *ſtigmas* two, on ſhort pedicels, nearly orbicular, greeniſh-yellow. *Capſule* one-celled, the edges of the valves being turned inwards, but not ſo far as to meet. *Seeds* roundiſh yellow[d].

Our Gerarde, remarked (1597) that "the flowers, (which he deſcribes as growing at the top of the ſtalk in a ſpokie buſh or rundell, of a red colour tending to purple), in the day time, and after the ſun is up do open themſelves, and towards evening do ſhut up again."

Native of moſt parts of Europe from Sweden and Denmark ſouthwards to Italy; and in all the temperate parts of Ruſſia, in dry paſtures: flowering from june to auguſt.

It is extremely bitter, with a diſagreeable flavour, whence Haller obſerves that it was called *fel terræ*, or gall of the earth, by the ancients. He alſo determines it to be the *graveolentia Centaurea* of Virgil, to which Lucretius give a more ſignificant epithet of *triſtia*, expreſſive of its extreme bitterneſs.

It is the baſis of the famous Portland powder, which prevents fits of the gout, when taken in a large quantity, and a long time together; but brings on hardneſs of the liver, palſy, and apoplexy. A tincture of the leaves, and the upper part of the root, is a good medicine to weak ſtomachs and cachectic habits. A decoction of the whole plant deſtroys lice, and cures the itch[e].

It is not uncommon with a white corolla: this alſo is ſometimes only four-cleft[f]. In boggy places it is found with a very ſhort ſtem, remarkably branched[g].

Although good reaſons be given by Mr. Curtis and Dr. Stokes, why this ſpecies ſhould be removed into the genus *Chironia*, yet averſe from change I have left it where Linneus placed it.

33. Stem ſcarcely an inch high. Root-leaves commonly in fours, ovate; ſtem-leaves oppoſite, obovate; all naked, quite entire. Flower terminating, ſolitary. Calyx five-cornered; ſegments acute, membranaceous. Corolla ſcarlet, with the ſegments very acuminate.

Native of Sweden[a].

The ſame with 32. β. but a diſtinct ſpecies.

34. Stem ſcarcely a hand high, round, and ſomewhat woody. Branches oppoſite, extremely ſimple, four-cornered, compreſſed, ſmooth and even. Leaves ſubſeſſile, lanceolate, ſmooth and even, longer than the internodes of the branches. Flowers ſeſſile. Calyx ſhort: ſegments acuminate, keeled, ſcarioſe at the edge. Corolla reſembling that of *G. Centaurium*, but ſulvous, with ſharp ſegments. Stamens in the throat. Style ſimple, filiform, ſhorter than the tube of the corolla. Capſule ſubglobular.

Native of the Eaſt Indies[a].

Linneus ſuppoſes the South American plant to be the ſame with this: it has however a more tender branched ſtalk than the American; the leaves are ſhorter and narrower; the corollas narrower, with a longer tube, and ſharp but not mucronate ſegments; the calyxes ovate-acute, with ſegments ſhorter than the capſule. In the American plant the ſtem is more ſtiff and robuſt, with the angles ſomewhat rugged not ſmooth and even; the ſegments of the calyx narrower and reflex[b]. See n. 37.

35. This reſembles *G. Centaurium*, but the flowers are peduncled and yellow; the leaves have not three nerves but one only[a].

Gerarde adds, that the tube of the corolla is longer, the flowers fewer in number, and the ſtyle double.—And Pallas, that the ſegments of the calyx are almoſt capillary; the tube of the corolla very narrow, dilated at the throat, the ſegments of the border nearly linear. Stem ſeldom more than a hand high, ſharply four-cornered, dichotomous at top. Leaves uſually oval, not ovate-lanceolate as in *G. Centaurium*. Peduncles thick, round, half an inch in length. Calyxes ſharply five-cornered, the ſegments ſubulate, as long as the tube of the corolla, the whole of which is an inch in length. Capſule cylindric, a little longer. The calyx is permanent, and ſeparable not without difficulty from the corolla.—There is a variety with two flowers at top, one terminating, the other lateral; ſometimes biſid, or three-flowered, the lateral flowers equally peduncled, the middle one ſeſſile[a].

Native of the ſea coaſts in the South of France, and Italy: about Naples, &c. alſo about Taſſis, and every where on the ſhore of the Euxine, where it has uſually white corollas[b]. In the Azores. Introduced in 1777, by Maſſon[c]. It is annual, and flowers in may. With us in july and auguſt.]

36. This is an annual plant, with an upright ſtalk, about a foot high, ſending out ſeveral branches towards the top. The flowers are produced from the ſide and at the top of the ſtalk in looſe irregular umbels; they are white, and about the ſize of thoſe of Common Centaury.——Native of the South of France and Italy.

[This has frequently purple corollas.

37. Native of America.—The Eaſt-Indian plant (n. 34.) is ſcarcely different. Root perennial. Stems ſeveral, a hand high, jointed. Leaves lanceolate. Flowers ſeſſile. Corollas yellow; the ſegments five and ſharp. Nectary a roundiſh ſcale annexed to the baſe of each filament within the tube of the corolla. Stigma capitate. Capſule half-two-celled[a].

Koenig ſent two plants from the Eaſt Indies, both agreeing with the Linnean character, but very diſtinct from each other. α. With the ſtalk angular at the baſe, but the upper part round; branched and ſtreaked: the leaves lanceolate and three-nerved: the flowers in whorls from the upper axils. This is the ſame with that which is deſcribed above.

β. With the ſtalk regularly four cornered, and perfectly ſimple. The leaves linear-lanceolate, fleſhy and nerveleſs. Flowers from every axil, of the ſame form and ſize as the others. This is the plant which is figured by Burman[a].

38. Size and ſtature of *G. Amarella*. Stem undivided, four-cornered with the corners membranaceous. Leaves three-nerved ſharped. Peduncles oppoſite, bearing at the end five flowers on very ſhort pedicels. Calyxes very ſhort, narrow. Corollas blueiſh, with a ſmall border, pervious at the throat[a].

According to Retzius, the *G. involucrata* or Friſs, figured alſo in fl. dan. t. 344. is entirely diſtinct from this; not having five flowers on a peduncle, but from one or two to ten; the leaves blunt, and the calyxes by no means very ſhort. He refers it rather to *aurea*, n. 27.—Found in Penſylvania by Kalm.

[a] Lyoni Mſs. [b] Stokes in With. [c] Scopoli. [d] Curtis and Stokes in With. [e] Withering. [f] Hudſon. [g] Ger. prov. Vaillant, Haller.

[a] Linn. ſuppl. [b] Vahl. [c] Linn. mant. [d] Gouan. [e] Pallas. [f] Hort. kew. [g] Linn. ſyſt. [a] Retzius. [a] Linn. ſpec.

39. A foot in height, tender and very ſmooth, with but few branches. Leaves ſubpetioled, ſmall: the upper ones more remote. Peduncle long, naked, terminating, one-flowered. Bractes two, below the flower, oppoſite, awl-ſhaped, upright. Calyx linear. Tube of the corolla funnel-form, longer than the calyx: border flat, beardleſs, yellow.

Found in the Azores by Maſſon[e]. See n. 35.

40. A very ſmall, filiform annual plant, ſcarcely branched, native of the mountainous woods of Martinico[b]: in the hollows of trees, ſcarcely pervious to the light. Stem upright, ſimple, four inches high, tender, ſhining, ſtraw-coloured, with oppoſite, very ſhort, remote ſtipules, at the joints. Flower terminating, ſolitary, erect, yellowiſh, inodorous[i].

41. So nearly allied, ſays Linneus, to *campeſtris* (n. 43.) as to be ſcarcely diſtinguiſhable, except by the calyx. Stem ſomewhat angular, branched; branches not longer than the leaves, (which are lanceolate) terminated by bunches of flowers. When this has a quadrifid calyx, it is in plants that are bitten down, and the diviſions are conſtantly equal: beſides the calyx of *campeſtris* is really four-leaved[k].

Root annual, twiſted, yellowiſh. Stem ſquare, erect, bearing ſeveral pairs of ſeſſile, ovate, three-nerved, dark-green leaves, and clothed from top to bottom with flowers, on ſhort, axillary, forked ſide branches, one being terminal. Calyx pale, with green ribs, and divided half way down into five lanceolate, nearly equal ſegments. Tube of the corolla twice as long as the calyx; ſegments of the border five, rarely three or four, horizontal when the ſun ſhines, the orifice crowned with a purple upright fringe, which conceals the ſtamens. Germ oblong: ſtyles very ſhort: ſtigmas divaricated[l].

From the variation of the number of parts in the corolla, which I had obſerved to be frequently four and five on the ſame plant, I was formerly led to a falſe concluſion, that this and the *campeſtris* are not ſpecifically different, but of this I now agree with Mr. Woodward that there is little doubt, the corolla varying ſo much as to number in this genus, as not to be depended upon for ſpecific diſtinctions.

In dry paſtures, through moſt parts of Europe, with us not uncommon, eſpecially in calcareous ſoils: flowering from july to ſeptember. Linneus ſays, in the autumn, with Colchicum or Meadow Saffron, later than campeſtris[m]. According to Ray, at the end of auguſt, or ſomewhat earlier.

A variety under the name of *the taller autumnal Gentian, with Centaury-like leaves*, is ſaid, in Ray's ſynopſis, to have been found near Welwyn in Hertfordſhire, and Bulchamp St. Paul in Eſſex: but it does not differ in any thing eſſential from the other.

Another variety is mentioned by Ray under the name of *G. fugax verna f. præcox*, differing in no reſpect from Amarella except in the time of flowering. This earlineſs may perhaps be owing to the plants having ſprung up in autumn, and ſtood the winter[n].

42. Upright, almoſt ſimple, a foot or leſs in height. Root ſlender ſomewhat woody. Stalk ſubquadrangular, a little contracted. Root-leaves ſmaller than the others, ovate, attenuated towards the baſe; the lower ſtem-leaves reſembling theſe; the reſt very remote from each other, oblong, five-nerved, ſeſſile; the uppermoſt ſomewhat claſping, and more lanceolate: they are all paler underneath, and ſometimes purpliſh. Flowers five on the top of the ſtalk between two pairs of leaves, on very long peduncles, and ſometimes from the next axils acceſſory little branches having one, two, or three flowers and one pair of leaves. Peduncles ſubquadrangular. Calyx angular, funnel-ſhaped, with two of the ſegments alternately broader, cordate-rounded, rolled back a little, and as it were eared. When the flower is five-cleft, three of the ſegments are ovate and ſmaller, the two others wider. Corolla uſually four-cleft, the tube whitiſh, the ſegments rounded, pale blue, extremely villoſe, at the baſe within, inſomuch that the tube is entirely cloſed with the long hairs. Anthers ſmall, brown, incumbent, not upright as in moſt of the ſpecies. Germ fuſiform, with a twin ſtigma. Near the ſea, it branches very much, and grows large; the farther it recedes from the ſea, the ſmaller it becomes; inſomuch that in moſſy wet ſituations inland, it is hardly an inch high, ſlender, and one-flowered. The maritime plants have generally the corolla violet or reddiſh, on open heaths at a diſtance from the ſea, it is pale blue or white, in marſhes commonly blue.—Certainly diſtinct from *G. campeſtris*.—Found throughout all Kamtſchatka, the iſlands towards Japan and America, and on the ſhore of America itſelf. The herb, both freſh and dry, is uſed by the natives as a ſtomachic and antiſcorbutic, and againſt vernal diarrhœas cauſed by feeding on fiſh; it is not however ſo bitter as ſome of the other ſpecies. It flowers the beginning of auguſt, and perfects its ſeeds in ſeptember[o].

43. Linneus can hardly be perſuaded that this is diſtinct from Amarella (n. 41.). He thinks it may be a variety, or perhaps a hybridous or mule plant. Scopoli boldly makes them one, becauſe the flowers cloſe at the approach of wet, in both; the ears of the corolla are finely jagged and upright; the edges of the calycine teeth are reflex; the baſe of the corolla adheres ſo cloſe to the calyx, that when torn away it carries off the inner ſkin along with it; and the ſtigmas are alike in form and poſition.

Others have no doubt of their being perfectly diſtinct. The calyx in this conſiſts of four ſeparate leaflets; the two outer oval-lanceolate, very large, the inner lanceolate, ſomething membranaceous, but one-fourth the breadth of the outer. Stem more angular, approaching to ſquare, and branched; the branches longer than the leaves, with the flowers more ſcattered; leaves ſhorter, and not ſo ſharply pointed. The flowers alſo are larger than thoſe of *Amarella*, though the plant is uſually ſmaller. Haller deſcribes it as extremely branched, and there are ſpecimens in England branched from the root to near the top; the branches long, with leaves and flowers ſcattered the whole length: but *Amarella* has the branches ſhort, even the lower ones not exceeding the length of the leaves from which they ſprang; the upper ones in general much ſhorter[p].

It is rather paler in colour, and never ſo tall as Amarella; the ſtem being leſs drawn up, the flowers fewer, and on longer flower-ſtalks, they appear more corymboſe; but the eſſential mark of diſtinction is in the calyx being deeply divided into four unequal ſegments, two external, oppoſite, oval, very large, completely enfolding and concealing the two others, which are lanceolate and not a fifth part of their breadth[q].

According to Pallas, it differs from *Amarella* in being taller and more branched, the leaves narrower, two ſegments of the calyx much larger than the others, the corolla ſmaller by half, paler, more frequently four-cleft, &c. It differs from the foregoing ſpecies, in the ſtem putting out flowering branches almoſt from the root, branches frequent, and leaves more lanceolate, the herb of a darker green and frequently purpliſh, the flowers ſmaller and ſubſeſſile, all the leaves of the calyx ſharp not alternately wide and heart-ſhaped, the ſegments alſo of the corolla ſharp. He adds—1. that it varies in ſize from a foot and half or a ſpan to three inches, and from a very branching ſtate to perfect ſimplicity.—2. in the ſize and colour of the corolla.—3. in the diviſion of the corolla into four or five ſegments; which is the caſe ſometimes even on the ſame plant.

Native of moſt parts of Europe from Lapland to Italy. Frequent in Ruſſia and Siberia to the lake Baikal: whereas Pallas has not obſerved *Amarella* in Siberia, nor in Ruſſia, except on mount Caucaſus. With us it is not ſo common as *Amarella*: but it

has

has been obſerved about Kendal and other places in the north, in Wales, Cheſhire, Cornwall, Suſſex, Stratton-heath and other places in Norfolk, Bury in Suffolk, &c.

In Engliſh Botany it is obſerved, that it grows in paſtures, more particularly towards the ſea; and that it is not ſo much confined to a calcareous ſoil as the Amarella. Linnæus ſays that it flowers in ſummer, after the ſolſtice. With us in ſeptember and octobor. Various months are ſet down by others, as april to june, and auguſt. Dr. Withering ſays that he has ſeen it flowering in a garden in octobor. This, as well as the two former, is annual.

According to Linneus, poor people uſe it inſtead of hops in beer: and according to Pallas, as a medicine, in common with many other ſpecies.

44. Root ſmall, round, ſtraight, not annual, (biennial *Pallas.*) Stalk from two to eight inches long (a foot *Haller,*) reddiſh, angular, ſmooth, leafy; ſometimes ſimple and one flowered, ſometimes with oppoſite branches, terminated by upright, ſeſſile, ſolitary flowers. Leaves ſeſſile, the lower ones ſhorter, obovate or ſpatulate; the reſt linear-lanceolate, acuminate, longer, quite entire, upright, ſmooth, not veined. Calyx quadrangular, lax, cleft into four parts down to the middle, green with a ſhade of duſky purple; the ſegments upright, lanceolate, acuminate. Corolla large, deeper or paler blue; the tube greeniſh, and obſcurely quadrangular, the ſegments oblong-obovate, blunt. Filaments pale, flat, ciliate at bottom: anthers oblong, twin, bay-coloured with a yellow pollen. Germ lanceolate, four-cornered but flatted, on a long pedicel. Capſule fuſiform, much flatted. Stigmas at firſt orbiculate, afterwards bifid and revolute[1]. According to Pollich there are only four ſtamens. Scopoli obſerves four nectareous glands at the baſe of the pedicel on which the germ ſtands.

The corolla varies in different countries: in America it is much ciliated: in Italy but little; in Iceland and Norway it is only ſerrate[2].

Pallas remarks, that this ſpecies is the connecting link between this genus and the Swertias: that it is very upright, with ſtiff branches, ſometimes exceedingly branched, much higher in Siberia and mount Caucaſus than the European plant, but with ſmaller flowers. Pallas has figured them both.

Native of Switzerland, Norway, Denmark, Germany, Auſtria, Carniola, Italy, Siberia, Caucaſus, Canada: flowering in auguſt and ſeptember: in Italy in octobor, and even till winter.—It is uſed officinally, by the natives; and deſerves a place in gardens from the beauty of the flowers[3].

45. Leaves lanceolate, three-nerved, connate. Flowers ſewer from the lower axils, but more crowded from the top of the ſtalk. At each bunch of flowers there are two ſmall leaves. Calyx ſhort, truncate, with the teeth remote and ſhort[4]. It is divided into the ſame number of ſegments with the corolla: that is, moſt frequently four, but ſometimes five. Corolla of a fine blue colour; between the ſegments and toothlets interpoſed, uſually bifid, but ſometimes ſimple, or trifid[5].

Pollich ſays that there are only four ſtamens. Both he and Leers remark, that the ſtigmas are rolled back in a ſpiral. The root is perennial; and it puts up ſeveral ſtalks, from a ſpan to a foot high and more.

The leaves being in pairs, and each pair croſſing the next at right angles, has given occaſion to the trivial name *Cruciata,* and the Engliſh name *Croſſwort Gentian.*

Native of Switzerland, Germany, Auſtria, Carniola, Hungary, the Apennines, Ruſſia, and Siberia: flowering in july and auguſt. In our gardens it flowers in june, and ſometimes in may. Cultivated in 1596, by Gerarde[6].

46. Native of Chili.

47. Root white, woody, ſimple or with large fibres. Root-leaves ſmall, narrow, oblong. Stalk about three inches high, ſimple or branched, at each joint a pair of ſmall, narrow, ſharp leaves. Flowers at the ends of the branches on long pedicels, yellow, ſmall, almoſt always cloſed, ſeeming, as far as could be diſcerned, to have five petals. Capſule elliptical[7]. The diviſion of the corolla is probably a miſtake; though perhaps it may be ſometimes five-cleft.

Every part of the herb is ſmooth. Flowers expanding only in bright ſunſhine[8].

Uſually branched, though ſometimes the ſtalk is ſimple. Corolla pale yellow, cut into four equal ſegments. Stamens four. Calyx cut almoſt to the baſe into four ſegments, rounded at the back[9].

It is a ſmall annual plant, growing in bogs, in Denmark, France, and England. Mr. Ray firſt remarked it towards the end of Cornwall (near St. Ives) in rotten marſhy ground. Dr. Pulteney ſent it out of Dorſetſhire. It is alſo found in Hampſhire and Devonſhire[10]. The time of flowering is July.

48. Root annual, fibrous. The plant has the appearance of *G. Centaurium.* Stalk erect, a ſpan high, dichotomous, quadrangular. Leaves ſeſſile, ovate, quite entire, ſmooth, ſomewhat fleſhy; the lower ones roundiſh; under the upper ramifications awl-ſhaped, very ſhort. Flowers ſeſſile, ſolitary in the diviſions of the ſtem, of a purple colour. Calyx bent in a little, ſtreaked, with four awl-ſhaped teeth. Tube of the corolla the ſame length with the calyx; border in two parts, each part divided in two; the two upper ones erect, the other two bent down incloſing a larger anther below, on the outſide ſpreading. Stamens four unequal, three within the tube, the fourth inſerted into the throat of the corolla, with a larger anther than the others. Germ oblong; ſtyle flexuoſe, longer than the ſtamens; ſtigma two-lipped, villoſe on the inſide, with the lips reflex. Capſule ſhorter than the calyx opening with a ſpring.

Native of Malabar, in cultivated fields. Diſcovered by Koenig[11].

49. Stem large, woody, round, with many, very long, climbing branches, without ſpines or tendrils. Leaves ovate-lanceolate, quite entire, ſmooth, aſh-coloured, oppoſite. Flowers lateral, with a ſmall, five-toothed calyx, and a bell-ſhaped corolla, with a wide tube, on the outſide aſh-coloured dotted with white, within filled up with denſe purple hairs; border ſpreading, white, bluntly five-cleft, ſhort, the ſegments uſually laciniate-plaited. Capſule roundiſh.

Native both of China and Cochinchina, climbing trees and hedges. It has an unpleaſant fetid ſmell, which is loſt in drying; and a very bitter flavour. In the Chineſe plant the leaves are often cordate, ſlightly emarginate at the baſe. It is tonic and ſtomachic[12].

50. Stem round, erect, ſimple. Leaves connate at the baſe, two inches long, very ſmooth, three-nerved. Flowers from the upper axils and at the end of the ſtalk; the lower ones ſolitary on each ſide, ſometimes only in one axil; terminating ones four, ſeſſile. At the baſe of each calyx two linear leaves, narrowed towards the baſe, ſhorter than the calyx; which is tubular, widening gradually upwards, with five teeth the length of the calyx itſelf, leafy, linear-lanceolate blunt, attenuated below. Corolla large, an inch and half wide, almoſt like that of *G. Japonaria.*—Native of Virginia.

51. Stem herbaceous, four-cornered with decurrent lines, ſmooth. Leaves ſeſſile, oppoſite, an inch long; the upper ones ſubcordate, all very ſmooth, ending in a ſhort dagger-point, and three-nerved. Peduncles at the ends of the branchlets, commonly in pairs, one longer, two-flowered, the other ſhorter, one-flowered; at the baſe on each ſide is a briſtle-ſhaped leaf. Calyx tubular, ſmooth. Corolla almoſt like that of *G. Centaurium.*—Native of the Eaſt-Indies[13].

52, 53. Natives of the Cape of Good Hope; obſerved by Thunberg.

PROPAGATION AND CULTURE.

Of this numerous genus not above ſixteen are cultivated in our gardens; and eight only are wild in this country. The greater part are natives of the European Alps. Several of theſe have been lately introduced from thence by Doctors Pitcairn and Fothergill, but it is difficult to preſerve ſome of them long in a ſituation ſo different from their proper one. Cluſius affirms, that he could not by any art make the ſecond or third ſpecies continue, or bear flowers in a garden.] The perennial ſorts in general may be propagated both from ſeed, and by offſets, taken off in autumn, which is the beſt ſeaſon for removing all theſe plants; but they ſhould not be removed or parted oftener than every third year, if they are expected to produce ſtrong flowers.

[The 1ſt, 34th and 35th with a few others not in cultivation at preſent require the protection of the green-houſe: the 16th and two or three others, little known, muſt be raiſed in a hot-bed, and kept in a ſtove; the reſt are hardy, and were they not difficult to preſerve, many of them would be very acceptable in borders of flowers.]

2. This plant delights in a light loamy ſoil and a ſhady ſituation, where it will thrive much better than in a light dry ſoil, or an open expoſure. It is propagated by ſeed, which ſhould be ſown in pots ſoon after it is ripe, for if it is kept till the ſpring, it will not ſucceed; theſe pots ſhould be placed in a ſhady ſituation, and kept clean from weeds. In the ſpring the plants will appear, when they muſt be duly watered in dry weather, and kept clean from weeds till the following autumn; then they ſhould be carefully ſhaken out of the pots, ſo as not to break or injure their roots; and a ſhady border of loamy earth ſhould be well dug and prepared to receive them, into which the plants ſhould be put at about ſix inches diſtance each way, obſerving to let the top of the roots be a little below the ſurface of the ground, then preſs the earth cloſe to the roots; but after this they will require no farther care, but to keep them conſtantly clean from weeds; and if the following ſpring ſhould prove dry, they ſhould be duly watered, which will greatly forward their growth. In this border the plants may ſtand two years, by which time they will be fit to tranſplant where they are deſigned to remain; therefore in autumn, ſo ſoon as their leaves decay, they may be removed; but as the roots of theſe plants run deep into the ground, like Carrots, there muſt be great care taken in digging them up, not to cut or break their roots, for that will greatly weaken, if it does not kill them. After the plants are well fixed in their places, they require no other culture, but to dig the ground about them early in the ſpring before they begin to ſhoot, and in the ſummer to keep them clean from weeds. The roots of theſe plants will continue many years, but the ſtalks decay every autumn; the ſame roots do not flower two years together, nor ſeldom oftener than every third year; but when they flower ſtrong, they make a fine appearance; and as theſe delight in ſhady moiſt ground, where but few ornamental plants will thrive, they ſhould not be wanting in good gardens.

3. to 13. may be propagated and cultivated in the ſame manner. [Pallas ſays that the 4th is eaſily raiſed from ſeed in the Ruſſian gardens.]

The 9th and ſome of the others muſt have a moiſt loamy ſoil, otherwiſe they will not thrive. [Cluſius relates, that he made the 9th flower in a garden, but that it drooped, and loſt much of its native vigour and elegance.]

The 11th not ſtriking its roots ſo deep into the ground as the officinal yellow Gentian, may be tranſplanted with leſs hazard, eſpecially if it be removed with a good ball of earth to the roots. In a ſtrong moiſt ſoil this will flower annually.

14. This is commonly propagated by parting the roots, but it muſt not be often tranſplanted or parted, in order to have it flower ſtrong; it ſhould have a loamy ſoil and a ſhady ſituation. It may alſo be increaſed by ſeeds ſown in autumn; in a good ſoil the plants will be ſtrong enough to flower the ſecond year, and theſe ſeedling plants will flower much ſtronger than thoſe which are propagated from offsets.

[This is one of the ſpecies beſt known, and much eſteemed for the brilliant azure of its flower, ſo large in proportion to the ſize of the plant.

Ray obſerves, that although it be a native of the higheſt Alps, yet it readily admits cultivation; and that it was much ſought after in his time by gardeners and floriſts for the beauty of the flower.

The other alpine *Gentianellas* may be increaſed and treated in the ſame manner. In common with other alpine plants, theſe love a pure air, an elevated ſituation, and a loamy ſoil, moderately moiſt; they do not proſper therefore very near London[e].

Cluſius affirms, in particular, that *G. verna* (n. 22.) rejects all culture.]

Several of theſe (as 28, 29, 30.) growing on ſpongy ground, it is difficult to cultivate them in gardens. The ſeeds muſt be ſown in pots, or upon a moiſt boggy ground in autumn, in the ſhade; when the plants come up the ſurface of the ground ſhould be covered with moſs, which ſhould be conſtantly kept moiſt.

44. and 45. may be increaſed and treated as n. 14.

[32. The common Centory cannot be cultivated in gardens, according to Bodæus a Stapel. Yet Mr. Ray raiſed it in his garden from ſeed, and it grew, flouriſhed, and perfected its ſeed.]

16. This is propagated by ſeeds, ſown on a hot-bed ſoon after they are ripe. The plants muſt be treated in the ſame manner as other tender annual plants from hot countries. If the ſeeds be ſown in autumn in pots placed in the tan-bed in the ſtove, they will ſucceed better than when ſown in the ſpring, the plants will flower early, and good ſeeds may be obtained.

Without thorns; leaflets lanceolate.

[e] Curtis.

DESCRIPTIONS, &c.

1. This is a thorny tree, fays Linneus, with pinnate leaves, and a drupaceous fruit, refembling the peach.

It is defcribed by Jacquin, as an inelegant tree, twelve feet high, upright, branched. Thorns few, awl-fhaped, frequently an inch long, thick on the trunk and branches. Leaves pinnate, midrib fmooth, grooved above, four inches long; leaflets commonly feven on each fide, with an odd one, oblong, blunt, fmooth, quite entire. Racemes fimple, denfe, axillary, three or four inches long. Flowers on very fhort peduncles, with corollas of a dirty fulvous colour, diffufing widely a moft fetid odour. The Drupe does not ill repreſent the freſh fruit of an Almond, the rind is very ſlightly tomentoſe, and of a greeniſh yellow colour. The pulp is ſoft, ſweet, yellowiſh, has a naufeous ſmell, and ſtains the hands with ruſt-colour not eaſily waſhed out. The nut or ſtone is whitiſh, adheres cloſe to the pulp, and contains a white kernel, that has a farinaceous aſtringent taſte. A plant with papilionaceous flowers, and a drupe for a fruit, is a great ſingularity[a]. —Native of Carthagena in New Spain.

2. This tree riſes to a conſiderable height, and towards the top ſends off ſeveral branches: the wood is hard enough to admit of being poliſhed: the external bark is ſmooth and gray; internally it is black and furrowed. Leaves pinnate[b].

Leaflets oppoſite, oblong-ovate, or lanceolate, acuminate, ſmooth above, nerveleſs beneath, on ſhort petioles. Flowers in cluſters, upon large branched ſpikes. Calyx very ſlightly five-parted, with ſhort, ovate diviſions. Corolla pale roſe-colour. Keel of the corolla ovate, ſpreading, very ſlightly divided into two parts. The fruit is a large ſubovate drupe, incloſing a woody nut.—Native of Jamaica[c]. Introduced in 1771, by Meſſrs. Kennedy and Lee[d].

In Jamaica it has the name of Cabbage-bark or Worm-bark tree. The bark, which has a mucilaginous ſweetiſh taſte, and a diſagreeable ſmell, was firſt noticed as a vermifuge by Mr. Peter Duguid; but Dr. Wright, who reſided a long time at Jamaica, has communicated the fulleſt information concerning this tree: according to him, the bark is powerfully medicinal, and its anthelmintic effects have been eſtabliſhed at Jamaica by long experience.

It may be given in decoction, ſyrup, powder or extract; but muſt be uſed with caution in ſmall doſes at firſt[e].]

GERANIUM. *(From γερανος, a crane, the fruit having the form of a crane's head and neck.)*
Lin. gen. n. 832. *Reich.* 897. *Schreb.* 1118. *Tournef.* 142. *Gærtn. t.* 79. *Cavan. diſſ.* 4. 194. *Juſſ.* 268.
Claſſ. 16. 4. Monodelphia Decandria.
Nat. order of *Gruinales.—Gerania.* Juſſ.

GENERIC CHARACTER.

CAL. five-leaved: *leaflets* ovate, acute, concave, permanent.
COR. *Petals* five, obcordate or ovate, ſpreading, regular.
Nectary five honied glands, faſtened to the baſe of the longer filaments.
STAM. *Filaments* ten, awl-ſhaped, connected ſlightly at the baſe, ſpreading at top, ſhorter than the corolla. *Anthers* oblong, verſatile.
PIST. *Germ* five-cornered, beaked. *Style* awl-ſhaped, longer than the ſtamens, permanent. *Stigmas* five, reflex.
PER. *Capſule* five-grained, beaked, the cells opening inwards, each having a ſimple naked tail fixed to it.
SEEDS ſolitary, ovate-oblong.

ESSENTIAL CHARACTER.

Cal. five-leaved. *Cor.* five-petalled, regular. *Nect.* five honied glands, faſtened to the baſe of the longer filaments. *Fruit* five-grained, beaked; *beaks* ſimple, naked, neither ſpiral nor bearded.

Leaves quinate and ternate, gaſhed, calyxes ten-angled.

DESCRIPTIONS, &c.

The genus of Geranium, as conſtituted by Linnæus, having become very unwieldy by modern diſcoveries, it is found very convenient to divide it; and a diviſion is commodiouſly made from this remarkable circumſtance; namely, that in ſome ſpecies all the ten filaments are fertile, whilſt in others three or even five of them are caſtrated, as Linneus ſpeaks; that is, are deſtitute of anthers. Hence three genera are now conſtituted out of one; *Erodium*, with five fertile ſtamens only, *Pelargonium* with ſeven, and this, retaining the old name, with all the ten fertile. There are alſo other marks of diſcrimination recited in their reſpective eſſential characters. Theſe three artificial genera or families, however, form but one natural family, agreeing in their five-leaved calyxes, their five-petalled corollas, their pentacoccous roſtrated fruits, and their general habit and ſtructure. They alſo agree in their inflorescence, the peduncles being curved downwards before flowering time, but when the flowers are about to open, the general peduncle firſt, and then each pedicel becoming erect.

1. Root perennial. Stems herbaceous, annual, diffuſely dichotomous, jointed, almoſt round and ſmooth. At the diviſions on each ſide is a lanceolate acuminate ſtipule. Leaves oppoſite, five-parted, divided into unequally pinnatifid acute ſegments. Peduncle longer than the leaves, from the axils, with two bractes at top. Calycine leaflets ſomewhat hirſute, with ſhort awns. Petals pale purpliſh, without any ſtreaks, ſcarcely longer than the calyx, either quite entire, or ſlightly emarginate *.]

Native of Siberia. Cultivated before 1768 by Mr. Miller, who received the ſeeds from Linneus. It flowers in june.

2. [Root perennial, ſomewhat woody. The whole plant ſet with white ſpreading hairs. Stems a foot or more in height, lax, ſpreading, branched, round, jointed, ſwelling at the joints. Leaves oppoſite, deeply lobed and cut, ſometimes ſeven-parted, the ſegments linear, the upper ſurface rough, the lower hairy, the edge alſo is hairy and entire. Peduncles axillary, much longer than the leaves, hairy, with a joint and two ſmall bractes more than half way down. Calycine leaflets oval, with membranaceous reddiſh edges, and terminated by a ſhort red awn. Petals obcordate, very large, pale red, with deeper veins, hairy at the baſe. The whole plant frequently turns red or purple after flowering †.

Native of many parts of Europe, in thickets and rocky paſtures, flowering moſt part of the ſummer, and often introduced into gardens as an ornamental plant.]

β. Miller inſiſts that the Lancaſhire Bloody Crane's-bill is a diſtinct ſpecies, the plants which he raiſed from ſeeds having always continued the ſame. The ſtalks are ſhorter, and ſpread flat on the ground; the leaves are much leſs, and not ſo deeply divided; and the flowers are much ſmaller, of a pale colour, marked with purple. It grows naturally in Lancaſhire and Weſtmoreland.

[There are other varieties of this ſpecies. One is mentioned by Ray, with larger, paler leaves, more deeply divided. And a ſecond, in Engliſh Botany, ſent by Mr. Davall from Switzerland; which has two flowers and four bractes from each joint, the calyx awned, the petals heart-ſhaped crimſon, veined, turning blue in decay, the ſeed-caſes nearly globoſe, briſtly at their ſummit, and the beak downy. The ſtem, flower-ſtalks, calyx and back of the leaves are clothed with white ſlender ſpreading hairs, the upper ſide and margin of the leaves with ſhort depreſſed briſtles.

3. This is a low ſucculent plant. Root ſimple, ſcarcely fibrous. Stem ſuffruticoſe, erect, branched, fenced all round with broad, ſmooth, irregular knots

* Jacquin. † Linn. Engl. bot. Withet. Stokes, Woodw. Mſs.

or

or tubercles, from the centre of which arises a very long, sharp, black spine. Leaves opposite, subsessile, wedge shaped, reflex, sinuate-crenate. Flowers solitary, peduncled. Calyx awned. Corolla purple, spreading, larger than the calyx: petals quite entire. Native of the Cape of Good Hope[c].

4. This is allied to Geranium glaucum (Pelargonium glaucum). Native of the Cape of Good Hope. Observed by Thunberg[d].

5. The whole plant is remarkably smooth, whence it had originally the name of *levigatum*. From a thick root, arises a very short stem, the thickness of a finger and succulent, whence spring branches two feet long, with very long leafless internodes. Root and stem-leaves numerous, subpeltate-palmate, five-lobed, lobes pinnate, pinnules gashed, having little notches ending in a very short awn: petioles longer than the leaves, thick, red, declining: stipules membranaceous, reddish, kidney-form. Upper leaves opposite, on petioles gradually shorter, subhastate-three-lobed; lobes pinnate, acute, the middle one longest: stipules short, ovate, concave. Flowers in the forks, and at the ends of the branches, on erect peduncles. Involucre four-leaved; leaflets ovate, short. Calyx ten-streaked, awned. Corolla pale blue, spreading, an inch and half in diameter; petals quite entire. Capsules smooth[e].

Native of Madeira. Introduced by Mr. Francis Masson in 1778. It flowers from may to september[f].

6. Root perennial, the thickness of a finger, becoming woody, dark purple on the outside, round, single or branched, having many long, round, thickish fibres. Hence springs a bundle of leaves, and several almost upright stems or rather scapes. These are all very soft and smooth, like the leaves of Marsh Mallow, with a very short close down. Most of the leaves are large subpeltate-seven-parted, on very long petioles; lobes oblong, a little narrowed towards the base, serrate-toothed, the edges tinged with pale red; the petiole round, strong, erect; as are also the scapes, which are somewhat higher than the leaves, silky-tomentose, quite simple, leafless, terminating in two peduncles, or else simply two-flowered. Bractes two, gash-multifid, at the foot of the peduncles: and others at the pedicels which are simple, entire, sessile, and form a sort of involucre. Flowers large, elegant, deep red[g], or bright purple. The whole plant when rubbed, emits an agreeable odour. [Native of Italy. Cultivated in the botanic garden at Oxford in 1658. It flowers in may and june.

7. Native of the Cape of Good Hope, where it was observed by Mr. Francis Masson. Introduced in 1787. It flowers in may and june[h].

8. Herbaceous. Stems filiform, somewhat knotty, having brittle-shaped scales at the knots. Lower leaves scattered, sprostrate, on long petioles, five-parted, multifid, hoary underneath, with linear segments. Peduncles scattered, either opposite to the petioles or axillary, long with bristle-shaped bractes, either all two-flowered, or else the upper ones four-flowered. Calyxes hairy. Beaks short[i]. Native of the Cape of Good Hope. Cultivated in 1704, by the Dutchess of Beaufort[k].

9. Root tuberous. Plant low, scarcely branched. Leaves petioled, divided into six larger segments, which are unequally subdivided into linear obtuse segments; at top, where the peduncles spring forth, subsessile. Flowers very abundant, terminating. Calyx awned[l].—Native of Italy and Silesia. Cultivated in 1596, by Gerarde. It flowers in may[m].

10. Stems upright, nearly cylindrical, from eighteen inches to two and even three feet in height, below woolly, and having a few long shining hairs on them; joints large, commonly tinged with red. Leaves soft, the younger ones silky, ribbed; the lowest on long petioles in pairs, the upper solitary; lobes mostly five, unequally toothed, the lateral ones lobed: the lower leaves have frequently six or seven lobes, and the uppermost only three or four. Peduncles very slender. Bractes flaccid, yellow, ovate-lanceolate, at the base of each peduncle. Calyx soft, thick set with short hairs terminated by little globules, interspersed with a few long woolly hairs; the leaflets are marked with three lines, and terminated by little blunt callous substances. Petals ovate, somewhat five-cornered, acuminate, waved at the edge, blackish purple, shining; claws white, marked with five lines, and woolly. Filaments purple, broad and woolly at the base, slightly united by means of five glands. Anthers whitish, with purple lines. Pollen greenish yellow. Germ woolly. Style green, shorter than the stamens till the time of flowering. Arils hairy. Seeds oblong-ovate[n]. Native of Switzerland, Hungary, Styria, England about Clapham and Ingleton in Yorkshire, Tovel near Maidstone, Lancashire, Cambridgeshire, Bedfordshire, Suffolk.

11. Linnæus separates this unwillingly from G. phæum, with which it agrees in many circumstances, and particularly in having the whole corolla spread out and dark coloured. It differs, however, in having the leaves rigid, the corolla more reflex and smaller, the petals suborbiculate, mucronate, quite entire, flat, the peduncles not solitary, two-flowered, but two distinct. Native of the South of Europe[o].

12. Stem a foot high, dichotomous or bifid, patulous, pubescent. Upper leaves alternate, five-lobed, wrinkled, tomentose, not spotted. Flowers drooping, on peduncles opposite to the leaves. Calyx awnless. Petals red, somewhat gashed, not longer than the calyx, reflex, gaping at the base. Stamens as long as, or longer than the corolla, nodding. Anthers yellow, with a brown edge. Native of Italy[p]. Cultivated in 1758, by Mr. Miller.

13. This is allied to the two last. The stem is the same; the lower leaves are conjugate, the upper ones solitary, narrower, deeply seven-cleft, with trifid serrate lobes. Stipules hirsute, green; those of the stem large, on the petioles small. Flower much larger, flat; the petals marked with a very small star, acuminate, broad, perfectly flat, elegantly plaited and serrate at the edge, pale blue (gris de lin) with a livid centre. Root thick, woolly, rufous. Native of Switzerland, about Aigle, &c.[q]. Introduced in 1775, by Drs. Pitcairn and Fothergill.

14. This is an herbaceous plant, having knobs like little bulbs at the origin of the branches and peduncles; whence the name. Lower leaves petioled, three-lobed, ovate-acuminate, serrate; the upper ones smaller, subsessile, the middle segment larger than the others. Peduncles axillary, very long, simple. Calyx streaked, awned, Corolla purple. Capsules smooth[r].

Stems smooth, shining, swelled at the joints. Lower leaves five-lobed, stem-leaves three-lobed, opposite; lobes lanceolate, divaricate, entire at the base, irregularly serrate upwards, each marked with three strong nearly parallel nerves, and cloathed with a few short stiff hairs arising from glands. Stipules and bractes alike, small and pointed. Peduncles short. Leaflets of the calyx awned, smooth. Petals red, obscurely and regularly crenate[s].

Native of Dauphiné and the mountains of Cumberland, flowering in july and august.]

15. Root perennial, sending up many branching stalks a foot and half high. Leaves light green, those on the lower part of the stalk have five lobes, and stand upon long foot-stalks; those on the upper part have but three lobes, sit closer to the stalks, and are sharply indented on the edges. Peduncles long and slender. Petals obtuse, deeply indented at top, of a dull white, finely reticulated with many purple veins. [The lobes of the leaves are gashed, and have a ferruginous or purplish brown spot at their base. Calyxes awned[t].

[n] With. Woodw. Mss. Haller. [o] Ibid. [p] Haller. [q] Woodw. Mss. [r] Linn. amoen. [s] Linn. mant. [t] Burman.

Native of Italy. *Cultivated in 1629* [a]. *It flowers in may and june.*]

16. Root perennial, thick. Leaves on long petioles, ſilvery, and ſhining. Flower ſtalks four or five inches high, with one or two ſmall leaves on them, like thoſe below, but ſeſſile; and terminated by two pretty large pale flowers, with entire petals that ſpread open flat. It flowers in june. [Native of monte Baldo, and Dauphiné.]

17. Root perennial. Stems ſeveral, about a foot high, or more, dividing by pairs; from the middle of the diviſions come out the peduncles, which are pretty long and naked, each ſuſtaining two pale purple flowers, with entire petals. It flowers in june. Native of Carolina and Virginia. [Cultivated in 1732, by James Sherard, M. D. [b].]

18. Root perennial, ſending up many ſtalks, which riſe near three feet high, [forked, tinged more or leſs with red; hairs on the upper branches white, terminated by minute dark red globules. Leaves on long foot-ſtalks, ſeven or five-lobed, theſe again lobed, the latter deeply toothed, hairy, marked beneath with ſtrong veins; diviſions of the upper leaves almoſt linear. Bractes four, lanceolate, acute. Flowers moſtly two, on very ſhort downy peduncles. Calycine leaflets lanceolate, ribbed, membranaceous at the edges, thick ſet with fine white hairs tipt by ſcarlet globules, and ending in an awn. Petals very large, inverſely ovate, marked with from ſeven to nine whitiſh lines, and a little hairy at the baſe. Filaments very broad, and ſomewhat concave at the baſe; the anthers are purple, and the pollen is purple [c].] The common colour of the petals is a fine blue, but it varies to white, and ſometimes to variegated or ſtriped. The flowers appear in may and june. Native of meadows, in moſt parts of Europe.

[19. The branches of this are extremely divaricated, biſariouſly and obtuſely angular. The petals are villoſe at the baſe, and are marked with three brown nerves.—It may be diſtinguiſhed from G. ſylvaticum (n. 21.), which it reſembles very much in the leaves, by the ſuperior length of the peduncles, which are alſo recurved before the flowers open, and are not erect, but declined; the petals likewiſe are entire, not emarginate.—Native of Germany, Ruſſia, Denmark [d]. Cultivated in 1732, by James Sherard, M. D. [e].

20. Native of Switzerland and Dauphiné. Introduced in 1775, by Drs. Pitcairn and Fothergill. It flowers in may [f].

Stems ſmooth, ſcarcely a foot high, forked. Lower leaves ſeven-lobed or ſeven-parted, on foot-ſtalks two inches long; upper five-lobed or five-parted, ſubſeſſile; uppermoſt quite ſeſſile, all pubeſcent on both ſides, ſubdivided, and the ſubdiviſions toothed: they are ſtrongly veined underneath. Stipules in pairs at the origin of each branch. A pair of bractes alſo to each peduncle, which is downy. Calycine leaflets ribbed, hairy, awned. Petals white, or ſlightly tinged with pale purple, marked with dark purple lines. Anthers violet. The ends of the calyx, the bractes, and the upper part of the peduncles are alſo purple.

21. Stems two or three feet high, covered with reflexed hairs, much branched. Lower leaves ſeven-lobed, middle five-lobed, upper three-lobed, ſeſſile, all ſlightly hairy, pale beneath, and veiny; the ſegments terminate in ſmall fleſhy glands. Peduncles ſometimes with more than two flowers. Bractes four, awl-ſhaped, ſmall. Calycine leaflets ribbed, membranaceous at the edge, mucronate; hairs on theſe, the peduncles, and the edges of the leaves, ending in ſmall globules. Petals large, purple, (ſometimes white, or variegated with white) ſlightly notched at the end, a little woolly at the baſe. Stamens all nearly equal. Aril hairy, with a brown elevated keel, but not rugged [g].

[a] Hort. kew. [b] Ibid. [c] Wither. & Woodw. Mſs. [d] Linn. [e] Hort. kew. [f] Ibid. [g] Wither. Woodw. Mſs. Engl. bot.

Native of mountainous woods and thickets in many, particularly the northern parts of Europe. With us in Durham, Weſtmoreland, Cumberland, Lancaſhire and Yorkſhire. About Ayſgarth Force, Wenſly dale; near Hales owen in Shropſhire; Holt wood in Leziate, near Lynn, Norfolk, &c. It flowers in june and july.

22. This ſpecies is twice as large as the common ſort, (n. 23.) and always nearly upright. Stem hairy, forked twice or thrice. Leaves hairy; the lower generally ſeven-lobed, theſe again trifid, with rounded or blunt diviſions, the middle one frequently crenate. The upper leaves are moſtly three-lobed, the lobes trifid, entire, the ſegments more acute than in the lower leaves, and the lobes more patent; they are often red at the edge. Peduncles ſolitary, from the forks, above from the boſom of the leaves, than which they are longer. Bractes four, acute. Calycine leaflets broad and ſhort, terminated by a red gland. Petals as long again as the calyx, purple, deeply cloven, the ſegments roundiſh and entire. The five outer filaments are ſhorter than the other five, and have abortive anthers. Aril even, ſharply keeled, ſcarcely pubeſcent [a].

Native of the South of France, the Pyrenees, and England. Near London about Chelſea, Brompton and Batterſea; near Enfield; Oxford; Bingley and Keighley in Yorkſhire, Edinburg.

23. Stems procumbent, round, reddiſh, from nine inches to a foot in length, villoſe, branched. Root-leaves roundiſh, hoary, and veiny underneath, deeply divided into ſeven ſegments, which are jagged: ſtem-leaves alternate, divided into fewer, narrower and more pointed ſegments. Stipules at each joint four, membranous and withering. Peduncles the length and form of the petioles, oppoſite to them, and biſid: pedicels nearly three time ſhorter, with ſmaller ſtipules, ſome of the hairs on which appear glandular when viewed with a glaſs. Calycine leaflets ovate, three-ribbed, hairy, unequal, terminated by a reddiſh and ſomewhat blunt point. Petals purple, obcordate, a little longer than the calyx; with ſmall claws edged on each ſide with hairs. Filaments unequal, broad at bottom, not perceptibly united. Anthers blue. Style with glandular hairs. Seed ſmooth, covered with a wrinkled aril.

G. molle when growing detached is procumbent, but among other plants it is drawn upright. It varies much in ſize, and the flowers vary in colour through many gradations of purple to pale red and white [b].

The peduncles alternating with the floral leaves, and the ſtem and branches cloathed with long ſoft hairs ſtanding at right angles with the ſtalk, ſufficiently diſtinguiſh this from the rotundifolium, with which it is frequently confounded [c].

It is the moſt common of all our Geraniums, on dry banks, under walls, in corn fields, and in paſtures: beginning to flower in april, and continuing through the ſummer.

24. Stems much branched, ſtraggling, but ſcarcely proſtrate. Leaves oppoſite. Peduncles alternate on the ſtem, and ariſing from the axil of a leaf, which is always ſmaller, and on a ſhorter foot-ſtalk than its oppoſite. Stem and branches covered with a very ſhort down, which feels extremely ſoft like velvet, when drawn through the fingers. The leaves are rounder, and of a paler colour; the ſeeds are dotted, ſo as to appear reticulated. Hairs on the aril ſpreading. Theſe marks diſtinguiſh it from the foregoing [d].

The filaments are clearly diſtinct at the baſe. The petals are fleſh-coloured or purple, varying to white, emarginate or obcordate. Mr. Woodward does not think that the diviſion of the petals is to be at all depended on. When freſh gathered it has a pretty ſtrong ſcent of muſk, but it ſoon goes off [e].

[a] Wither. Stokes, Curtis, Engl. bot. [b] Curtis. [c] Woodw. Mſs. [d] Ibid. & Engl. bot. [e] Withering.

On

On walls, roofs, banks, and in ſandy paſtures, about Iſlington, Hackney, Batterſea, Wandſworth, Mortlake, Kew, &c. near London; Church Bramton in Northamptonſhire; about Bath and Briſtol; in Suffolk common.

25. Stems ſpreading, about a foot long, pale green or ſometimes reddiſh, very ſlightly downy, branched. Leaves roundiſh, ſeven-lobed; lobes trifid, obtuſe, ſome of them more deeply divided, the ſinuſes rather acute; veiny, villoſe, ſoft, pale green; the root-leaves on very long petioles, the ſtem-leaves oppoſite, unequal, nearly as long as the peduncles; their lobes more acute. Stipules lanceolate, broad at bottom, red, ſhining; ſegments ſharp, edged with hairs. Flowers very ſmall, purpliſh blue, on peduncles from the axils, about an inch long. Bractes like the ſtipules, but ſmaller. Calycine leaflets ſtriated, covered with hairs which point upwards, white on the edge, the two outer ones wider than the reſt. Corolla a little larger than the calyx, bell-ſhaped and open; petals obcordate, emarginate. Filaments five longer, with ovate, blue anthers; five ſhorter and ſterile. Seeds kidney-ſhaped, ſmooth, reddiſh; aril pale brown, even, with white hairs preſſed cloſe to it.

It differs from the *molle* in having the leaves more divided, of a paler and more yellow colour; the flowers much ſmaller, of a bluer and leſs brilliant hue; the ſtems ſcarce perceptibly hairy, or but ſlightly pubeſcent: the leaves in general grow oppoſite, but frequently not ſo towards the top of the ſtem, and are more open behind: the fertile ſtamina are never more than five; and the aril is not tranſverſely wrinkled as in the *molle*, but comparatively ſmooth. It forms a larger tuft than the *molle*, and ſometimes varies with white flowers, as that does. It is alſo equally common in many places; particularly on the weſt ſide of London, in neglected gardens and fallow fields; flowering in june and july[1].

Probably ſmall varieties both of *molle* and *rotundifolium* have been taken for this. The figure, in the third edition of Ray's ſynopſis, by Dillenius, ſeems to be one of the latter. There are two ſpecimens in the Linnean herbarium, one of which is clearly ſo; the other appears to be diſtinct[2].

26. Stems and leaves ſmooth and ſhining as if varniſhed, whence its ſignificant trivial name; they are, however, ſlightly hairy. Leaves kidney-ſhaped, moſtly five-lobed, theſe again divided half way into three lobes, the middle one having uſually three notches, the ſide ones entire: it varies, however, from this diſpoſition. In rocky ſituations the leaves are only half an inch broad, and not ſo much divided. Flowers on ſhort ſpreading peduncles, with very minute bractes. Petals roſe-coloured, emarginate. The aril has ſeveral rugged longitudinal ribs, and is hairy at top. The whole plant is ſometimes red[3]. Native of moſt parts of Europe, on walls, roofs, banks, in rocky and ſhady places, and in a chalky ſoil among corn. It flowers from june to auguſt.

27. Slender, moſtly procumbent, with ſmall, rigid, cloſe-preſſed hairs. Leaves a little hairy on both ſurfaces, divided to the foot-ſtalk into ſeveral lobes, theſe again divided with linear ſegments. Stipules lanceolate, red, two on each ſide of the ſtem. Peduncles very long. Pedicels much divaricated. Calyx five-angled, very large and ſwelling; ſometimes hairy, membranous at the edges, terminated by ſhort awns reddiſh at the ends. Petals reddiſh blue, or pale purple, marked with three lines, emarginate, the little tooth between the lobes not very pointed. Anthers blue. Arils ſmooth, ſlightly keeled. Seed covered with minute punctures[4].

Native of moſt parts of Europe, in corn fields and paſtures, and under hedges. It flowers from june to auguſt.

28. The leaves reſemble thoſe of *Potentilla argentea*, ſome of them are five-cleft beyond the middle, and pinnatifid; others are digitate, with linear pinnatifid pinnas. The ſtipules are trifid. Native of the Cape of Good Hope[5].

29. Stalks many, about a foot long, ſpreading, roundiſh, pale green, here and there reddiſh, beſet with ſhort white hairs pointing downwards, jointed; with alternate, ſpreading branches. Leaves oppoſite, on long foot-ſtalks, divided to the baſe into five ſegments, and theſe again divided uſually into three (or three to ſix) ſmaller ones, which are uſually entire, but the middle one is ſometimes again ſubdivided; all of them are linear, but unequal, ſomewhat pointed, with hairs on both ſides pointing upwards, red on the edges and at the tip, the ſinuſes obtuſe; the ſegments of the root-leaves approach nearer to each other, and are blunter; foot-ſtalks ſpreading, a little flattened, hairy like the ſtalk. Stipules two-lobed, with a broad white baſe, the lobes ſemicordate, acuminate, red, ſhining, having a whitiſh line on the back, which together with the margin is edged with hairs. Flowers ſmall, purpliſh red, on peduncles ſhorter than the leaves. Bractes two, red, minute. Calycine leaflets three-ribbed, awned, beſet with glandulous hairs. Corolla a little ſhorter than the calyx; petals oblong-cordate, emarginate. Anthers nearly ovate, blue. Piſtil woolly, with glandulous hairs. Stigma reddiſh. Aril villoſe, with the ſame glandular hairs.

G. diſſectum can ſcarcely be miſtaken for any other; it is, however, not only diſtinguiſhed by its finely divided leaves, whence its trivial name, but by the flowers, which are uſually of a bright colour, being on ſuch very ſhort foot-ſtalks as to appear ſeſſile among the leaves; the petals alſo are uſually ſhorter than the calyx by the awns of the latter, which are unuſually long: the calyx and ſtyle are thickly covered with viſcid hairs, and the hairs on the ſtalk do not ſpread horizontally, as in many other ſpecies, but obviouſly point downwards. It varies greatly in ſize; alſo with fleſh-coloured and white flowers. Native of moſt parts of Europe, by road ſides, on banks, in fallow fields, and on the borders of paſtures, flowering in may and june till auguſt[6].]

30. This greatly reſembles common Dove's-foot Cranes-bill, but is ſmaller, and the branches are ſhorter: the flowers are very ſmall, of a pale blue colour. Seeds black, with ſhort erect beaks. Native of Carolina.

31. Stems many, branched. Leaves five-lobed, crenate, on long foot-ſtalks, and moſtly oppoſite. Flowers on long, ſlender, axillary peduncles. Corolla of a fine blue colour. Arils and beaks black. Native of Bohemia. [This, however, is doubtful. Cultivated in 1683, by Mr. James Sutherland. It flowers from june to auguſt[7].

32. Stems ſpreading, branched, blood-red, hairy, particularly in young plants. Leaves oppoſite, hairy eſpecially when growing in the ſhade, firſt three-lobed, the lobes again three-lobed, the lower ones diſtinct, the upper ones lengthened with confluent lobes, the jags terminated by a ſmall red ſpine. Stipules four at each joint, two on each ſide. Peduncles very long. Pedicels ſhort. Calycine leaflets ovate-lanceolate, nerved, hairy, ending in a long awn, the ten angles formed by the firſt and third outer leaves being each folded into three keel-like angles, the ſecond and fifth each into one, and the fourth into two; the angles become more evident as the ſeeds ripen. Petals roſe-coloured (varying to white) ſpreading and equal, the lamina ſomewhat heart-ſhaped, the claw long and linear, the middle part of it prominent, grooved, and ſpreading into three whitiſh nerves. Filaments not very evidently united at bottom; anthers red or purpliſh, with yellow pollen. Style villoſe: ſtigmas fine crimſon, a little turned back. Seeds brown, ſmooth, ovate, flattened on one ſide, in a wrinkled aril.

[1] Curtis. [2] Woodw. Mſs. [3] Ibid. and Engl. bot. [4] Wither. Woodw. Mſs. Engl. bot. [5] Linn. amoen. [6] Curtis. [7] Hort. kew.

The

The whole is beſet with pellucid hairs, but becomes ſmoother as the plant grows older. It is commonly red at the joints, and the whole plant is frequently red. It has a diſagreeable rank ſmell when bruiſed.

A decoction of Herb Robert has been known to give relief in calculous caſes. It is conſiderably aſtringent, and is given to cattle when they make bloody water, or have the bloody flux. Mr. Curtis aſks whether this practice may not originate from the old notion of ſignatures[a].

Native of all Europe, in woods, under hedges, in hollow trees, on walls and the roofs of houſes, among rubbiſh, and in ſtony places, flowering from april through the whole ſummer.

The name *Stock-hill* is ſet down in Dr. Witherings arrangements, which is probably a corruption of *Stork-bill*.

β. In the variety which occurs near Swanning in Dorſetſhire, and on the ſhore of Selſey iſland, the whole plant is ſhining; the leaves ſmaller, and more deeply divided.]

PROPAGATION AND CULTURE.

The annual ſorts of Geranium may be increaſed by ſeeds, and if theſe be permitted to ſcatter, the plants will come up without any farther care. The perennial ſorts, which are more numerous, may be increaſed the ſame way, or by parting the roots in autumn. They may be planted in almoſt any ſoil or ſituation, and require no other culture but to keep them clean from weeds. Many of them, indeed, are common weeds. but even ſome of theſe have beauty enough to recommend them to a place in a garden, particularly the ſecond, eighteenth, twenty-firſt and twenty-ſecond ſpecies.

Moſt of the Erodiums alſo are hardy, and may be increaſed in the ſame manner; the annual ſorts by ſeeds, and the perennial by dividing the roots. Some of them, as the craſſifolium, incarnatum, glaucophyllum and chamædryoides, require the protection of a green-houſe. The ſeeds of the glaucophyllum ſhould be ſown on a moderate hot-bed in ſpring, and when the weather is warm, the plants ſhould be carefully tranſplanted on a ſheltered border.

[GERANIUM. See *Erodium*, *Grielum*, *Monſonia*, & *Pelargonium*.

GERARDIA. *(So named by Plumier in honour of John Gerarde, our old Engliſh botaniſt, author of the Herbal, 1597, folio, and a great cultivator of exotic plants, of which he publiſhed a catalogue in 1596.)*

Nigrina viſcoſa. *Lin. ſyſt. edit.* 13. 167.
Melaſma ſcabrum. *Berg. cap.* 162. *t.* 3. *f.* 4.
Scabrous, leaves lanceolate, ſerrate at bottom, ſtalk four-cornered.

DESCRIPTIONS, *&c.*

Stalk upright. Leaves oppoſite. Flowers ſolitary, axillary, ſomewhat bell-ſhaped[b].

1. Root-leaves as on the ſpike. Bractes imbricate, one-flowered. Border of the corolla wheel-ſhaped. It may be doubted whether it be not of another genus[c].

Linnæus recommends a farther examination of the fructification.—Native of South America.

2. Stalk villoſe. Leaves pinnate at the baſe, above gaſh-pinnatifid, villoſe; pinnas acute, ſerrate. Flowers axillary, peduncled, ſolitary. Peduncle many times ſhorter than the leaves. Corolla purpliſh.—It differs from *G. pedicularia* in having a ſimple ſtalk, peduncle ſhorter than the leaf, and gaſh-pinnatifid leaves, with ſerrate pinnas.—Native of Japan[d].

3. Stem a foot high, obtuſely four-cornered, upright, even, with few alternate branches. Leaves oppoſite ſmooth. Flowers axillary, from the middle to the top of the ſtem, oppoſite, directed one way, on very ſhort peduncles. Calyx tubular, with five linear teeth the length of the calyx. Corollas oblong, with a gaping mouth, and a five-lobed rounded border, the two upper lobes ſhorter. Anthers twin, two having the ſpine of the baſe extended downwards, the other two having the ſpine parallel to the anther. Style the ſame length with the ſtamens. Stigmas blunt[e].—Annual. Native of the Eaſt-Indies.

4. Found at the Cape of Good Hope, by Thunberg.

5. Root annual. Stalks a foot high, filiform, either very ſimple, or brachiate, ſmooth. Leaves quite entire, oppoſite, but often alternate alſo. Flowers oppoſite, on one-flowered, filiform peduncles, or elſe ſeſſile. Calyxes ſmooth, ſmall, bell-ſhaped, five-toothed. Corollas very deep purple, either wheel-ſhaped or bell-ſhaped, or tubular; thus

[a] Curtis & Withering.

[b] Juſſieu. [c] Ibid. [d] Thunberg. [e] Linn. amœn.

varying

varying much in figure[a].—Native of North America.—It is the only species of this genus yet cultivated among us, and was introduced in 1772, by Samuel Martin, M.D. It flowers in july and auguſt[b].

6. Found at the Cape of Good Hope, by Thunberg[c].

7. Stalk a foot high or more. Leaves ſubpetioled (like thoſe of Lycopus or Jacea), gaſhed at the baſe like pinnate leaves with patulous ſinuſes. Spike terminating, lax, conſiſting of oppoſite large, yellow flowers. Anthers ſtanding downwards into two thorns. There is no fifth ſtamen. Native of North America[d].

8. Corollas pubeſcent on the outſide, oblong, patulous. Teeth of the calyx crenate. It dries black, like a Pedicularis, and is allied to *P. triſtis*. Native of North America[e].

9. Stem roundiſh, upright; with ſhorter branches. Leaves petioled, ſharp, above an inch wide, deeply ſerrate, ſubvilloſe. Racemes terminating, ſolitary, compoſed of oppoſite flowers on very ſhort peduncles. Calyxes five-parted, ſharp, the uppermoſt diviſion largeſt. A filiform bracte or two, of the ſame length with the calyx, is cloſe to it, hiſpid like that, with glutinous hairs.—Native of China[f].

10. This was formerly made a diſtinct genus by Linnæus, under the name of *Nigrina*, but he was afterwards of opinion that it could not be ſeparated from the Gerardias.—Native of the Cape of Good Hope[g].

Calyxes calycled.

DESCRIPTIONS, *&c.*

Theſe plants have the ſame habit with Tragopogon and Scorzonera. The flowers in the two firſt ſpecies not yellow, but red: theſe are annual. The third ſpecies is perennial. All of them are natives of Italy.]

1. This has an upright ſtalk more than a foot high, with long graſs-like leaves. The ſtalk branches at top into two or three diviſions, each terminated by one fleſh-coloured flower. [The whole plant is ſmooth. Leaves narrow-enſiform, acuminate, ſeſſile. Calyx uſually ſeven-leaved. Seeds even, ſcarcely rough; the rays ſtiffly ſpreading, the middle ones erect[a].]

2. Stalk upright, a foot high. Leaves narrow. It ſeldom divides into branches, but is terminated by one flower.

[Theſe were cultivated by Mr. Miller in 1759.

3. Root perennial. Stems ſeveral, branched.—Flowers terminating, nodding before they open. Calyx calycled, with numerous floſcules[b]. Leaves ſublinear, acuminate, the loweſt ſtem-leaves and the root-leaves channelled beneath, and hairy on both ſides, the upper ones flat, and a little hirſute only on the back. Stems aſcending, round, a foot and half high, villoſe and leafy. Peduncles almoſt leafleſs, ſtriated, pubeſcent, terminated by a ſingle flower. Each calyx has about eight leaves, lanceolate, acuminate, with a membranaceous edge. Fruiting calyx angular. Corolla yellow on both ſides. Receptacle naked. The ſeeds have a long, ſtiff, ſubplumoſe egret, yellow at the baſe, purple at top[c].

Introduced in 1774, by Joſeph Nicholas de Jacquin, M.D. It flowers in june[d]. The two others flower later, in july or auguſt.

Leaves ovate-lanceolate, crenate, hirsute, peduncles lateral, very long, corymbiferous.

4. Gesneria Craniolaria.
Swartz. prodr. 89. *Plum. gen.* 27. *t.* 137. Craniolaria fruticosa. *Lin. spec.* 861. *Reich.* 3. 141. *Mill. dict. n.* 2.
Leaves wedge shaped, oblong, tooth-laciniate, peduncles terminating, corollas bell-shaped.

[5. Gesneria grandis.
Swartz. prodr. 89.
Leaves broad lanceolate, very long, toothletted, rough-haired above, rugged beneath, peduncles terminating; stem arborescent.

6. Gesneria scabra.
Swartz. prodr. 89.
Leaves ovate-lanceolate, serrate, rugged, peduncles axillary, corollas cylindric, recurved.

7. Gesneria corymbosa.
Swartz. prodr. 89.
Leaves ovate, acute, serrate, scariose, sharp, peduncles many-parted, flowers in corymbs.

8. Gesneria exserta.
Swartz. prodr. 89.
Leaves ovate-lanceolate, crenate, smooth, peduncles three-flowered, genitals twice the length of the corolla, capsules ovate.

9. Gesneria calycina.
Swartz. prodr. 90.
Leaves lanceolate-ovate, acuminate, serrate, smooth, peduncles three-flowered, genitals longer than the corolla, calyxes bell-shaped, capsules cylindric.

10. Gesneria ventricosa.
Swartz. prodr. 90.
Leaves elliptic, acuminate, crenate, smooth, peduncles four-flowered or thereabouts, segments of the calyx awl shaped, elongated, corollas ventricose.

11. Gesneria pulchella.
Swartz. prodr. 90.
Cyrilla pulchella. *L'Herit. fl. nov.* 147. *t.* 71. *Ait. hort. kew.* 2. 330.
Columnea erecta. *Lamarck. encyl.* 2. 66. *n.* 2.
Achimenes 2. *Brown. jam.* 271. *t.* 30. *f.* 1.
Herbaceous, leaves ternate, ovate, acute, serrate, villose, peduncles axillary, one-flowered.

12. Gesneria pumilla.
Swartz. prodr. 90.
Stemless, leaves ovate-wedge-shaped, crenate, subsessile, peduncles subbiflorous, shorter than the leaves.

DESCRIPTIONS, &c.

These are either herbs or shrubs. The flowers are on axillary peduncles, many together, and accompanied with bractes[a]. They are natives of South-America and the West-Indies.

1. Root diffused, creeping. Stem branched, naked at bottom. Leaves aggregate at top, deciduous. Peduncles branched, three-flowered.]

This is of much humbler growth than the third species; the leaves are much smaller; and the flowers are deeper cut at their brims. It was found growing naturally by the late Dr. Houstoun at Carthagena in New Spain. [Also by Sir Hans Sloane in Jamaica. Cultivated by Mr. Miller before 1733.

2. Stem round, woody, having a clay-coloured bark, with some furrows in it, rising three or four inches high, having at the top very many oblong leaves, standing very thick, without any order, on foot-stalks a quarter of an inch in length, covered with a reddish wool-like moss. They are seven inches long, and an inch and half broad near the farther end, whence they narrow to a point, and they also grow gradually narrower to the foot stalk. From the axils come out small peduncles, branched, sustaining scarlet flowers an inch long, which are followed by a short, fungous, cornered seed-vessel, having no distinct cells, containing many small, oblong yellowish seeds[b].

Browne calls it *small tufted Gesneria, with scarlet flowers*; and observes that the stem is always simple, creeping along the rocks, and bearing a pretty large tuft of leaves at the extremity, with single flowers springing from each axil.

Swartz describes the stem as very short at first, but as it advances becoming frequently a foot in length, and in this state covered with withered leaves and calyxes. The leaves are rugged and wrinkled. The calyx is five-parted; the parts linear, and very long. The limb of the corolla is contracted and five-notched. The filaments are nearly equal; the anthers roundish and connected. The germ is ovate; the style longer than the corolla. The capsule is covered with the calyx, is five-cornered, grooved, and two-celled.

Native of Jamaica.]

3. This rises with a shrubby stalk to the height of six or seven feet, dividing into two or three irregular branches, covered with a russet wool. Leaves seven or eight inches long, and two and a half broad in the middle, having a russet woolly midrib; they are placed on every side the branches without order, and on short foot-stalks: towards the ends of the branches, at every joint, from the axils, come out the peduncles; they are naked, and nine inches in length, branching at the top into many smaller peduncles, each sustaining a single flower of a dusky purple colour. Capsule roundish, sitting close in the calyx, the divisions of which rise above it.

[Swartz describes the stem as upright, a yard in height, suffrutescent, round, wrinkled and hirsute. Leaves scattered towards the end of the stalk, on very short petioles, spreading, acuminate, serrate, nerved and netted veined, somewhat clammy, softish, tomentose-hirsute, hoary underneath. Stipule roundish, revolute, crenate, tomentose. Peduncles erect, round, hirsute, clammy, forming a sort of corymb at top, with unequal, subdivided pedicels. Corolla irregular, subcampanulate, gibbous at the base, and under the limb: the two upper segments approximate, so as to form one as it were that is bifid, arched in the middle, spotted on the inside with yellow and dark purple; the three lateral ones are spreading, ovate, acute, the lowest ventricose underneath; the tube is spotted within. The two anterior filaments are longer than the two others, and are bowed in towards the pistil. Anthers convex. Style longer than the corolla. Stigma cut half way transversely. Capsule crowned with the calyx, two-celled:—according to Gærtner, one-celled, opening at the top with an oval hole, of an ovate-globular shape, covered with the tomentose calyx saftened close to it, and serving as a bark, the teeth of it forming a sort of crown above it: there are two fungous opposite receptacles, saftened to the side of the capsule, separated near the axis, and dividing the capsule into two cells communicating with each other. This plant bears some affinity to the Saxifrages in the situation of these receptacles, and in the opening of the capsule.

This is called by Browne, *hairy erect Gesneria, with open flowers.* It is a native of Jamaica, and was cultivated by Mr. Miller in 1759[c].]

4. This sort grows naturally at the Havannah, and in some of the other islands in America. It rises with a shrubby stalk to the height of ten or twelve feet, dividing upwards into a few branches, which are garnished with spear-shaped leaves, cut on their edges; these are soft and hairy. The flowers are produced from the side of the branches, growing

[a] Jussieu. [b] Sloane. [c] Hort. kew.

ſeveral together on the ſame foot-ſtalk; they are ſhaped like thoſe of the Foxglove, of a greeniſh yellow colour, with brown ſpots on the inſide; the flowers have a ſwelling tube, which is recurved, and the brim is ſlightly divided into five unequal ſegments. Theſe appear in July, but are not ſucceeded by ſeeds in England.

[5 to 12. All theſe are natives of Jamaica, and the tenth of ſome other iſlands in the Weſt-Indies; they were all obſerved by Swartz. They are ſhrubby, except the eleventh, which is annual, according to Swartz, but perennial, as marked by others.—Browne deſcribes this as having a ſlender even ſtem, ſeldom riſing above ten or fourteen inches in height; and throwing out a beautiful ſingle reddiſh flower from the axil of each of the upper leaves. Filaments longer than the corolla, and ſomewhat twiſted as they riſe.

Monſ. Lamarck ſaw it in flower in the garden belonging to Monſ. L'Heritier, who named it Cyrilla pulchella; which ſee. He firſt received it in flower by means of Brouſſonet from England; where it was introduced in 1778 by Mr. William Forſyth [a].]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds, which muſt be procured from the countries where they grow naturally. They ſhould be brought over in their capſules, for as they are very ſmall and light, when they are ſeparated from the partition to which they adhere, they ſoon loſe their vegetative quality.

The ſeeds ſhould be ſown in pots filled with light earth, and plunged into a hot-bed of tanner's bark as ſoon as they arrive, for they ſometimes lie long in the ground; thoſe which I have ſown in autumn came up the following ſpring; therefore when they happen to arrive here at that ſeaſon, the pots in which the ſeeds are ſown ſhould be plunged into the tan-bed in the ſtove, and during the winter the earth ſhould be now and then gently watered to prevent it drying too much, but it muſt not be too moiſt. In the ſpring the pots ſhould be removed out of the ſtove, and plunged into a freſh hot-bed, which will bring up the plants ſoon after. When theſe are fit to remove, they ſhould be each planted into a ſeparate pot, and plunged into a good hot-bed of tan, obſerving to ſhade them till they have taken new root; then they muſt be treated in the ſame way as other tender plants from the ſame countries.

In autumn they muſt be plunged into the tan-bed in the ſtove, where, during the winter, they ſhould have but little water given to them; for if they receive much wet, it will deſtroy them. In this ſtove the plants muſt conſtantly remain, for they will not thrive if they are kept out of the tan. In the ſummer they ſhould have free air admitted to them at all times when the weather is warm; and they muſt be frequently refreſhed with water during that ſeaſon, but it muſt not be given to them in too great plenty. As the plants advance in growth they will require larger pots, but there muſt be care taken not to over-pot them, for they will not thrive in large pots. With this management the plants will flower the ſecond year, and may be continued three or four years, but they are not of long duration in their native country.

The fourth ſort ſeldom flowers till the third year, and as it does not produce ſeeds here, it is with difficulty preſerved in the European ſtoves.

[The eleventh ſort deſerves to be cultivated in the flower-gardens of America. It thrives beſt in a cool gravelly ſoil, well furniſhed with moiſture, and intermixed with rich mould [b].

Lin. ſyſt. 339. *ſuppl.* 198.
Papiria lanceolata. *Thunb. act. lund.* 1. 112.
Leaves lanceolate, flat, ſegments of the corolla lanceolate.

DESCRIPTIONS, *&c.*

All theſe plants have the habit or air of *Colchicum*, but are ſufficiently diſtinguiſhed from it, by having a monopetalous corolla, and a berry for a fruit. There is but one flower on a naked ſtalk; and the fruit has a grateful odour, with a pleaſant taſte. They are natives of the Cape of Good Hope, where they were obſerved by Thunberg, who has figured and deſcribed them [c]. The third ſpecies only has been long known in Europe. That was cultivated in 1780, by the late Dr. Fothergill. The two firſt were introduced here by Mr. Francis Maſſon, in 1777 and 1778 [d].]

Stems one-flowered, awns straight, villose, leaves pinnate, gashed, hairy, runners creeping.

DESCRIPTIONS, *&c.*

These are perennial herbaceous plants. The leaves usually unequally pinnate, with the terminating leaflet larger than the rest. The stipules fastened to the petiole. The peduncles terminating or axillary, supporting few flowers, sometimes only one. Natives of Europe and North America. Flowering from may to september.]

1. Stem a foot and half or two feet high, branching at top into small peduncles, each terminated by a small white flower.

[This species differs from *G. urbanum*, which it otherwise much resembles, in having white petals shorter than the calyx; the flowers nodding during flowering time; the peduncles being thicker towards the flower; the seeds hairy, and the root-leaves subbipinnate*.

Parkinson mentions an Avens from New-England brought by John Newton a Chirurgion of Colliton, but he says it differs from G. rivale only in being taller and greater.

Cultivated in 1739 by Mr. Miller. It flowers in july and auguſt: and is a native of North America†.

2. This has the habit of G. urbanum. Stems upright, round, a foot and half high and more, most of the branchlets ending in one-flowered peduncles. Root-leaves pinnate and petioled, with the outmost leaflet very large, rounded and lobed, the side ones ovate, differing much in size, all sessile and unequally serrate: sometimes the extreme leaflet is trifid-palmate, sometimes but more rarely, all the leaflets are deeply gashed. Stem-leaflets lanceolate and acute. Uppermost stem-leaves simple, and below these ternate. Stipules sessile, gashed. Petals

* Linn. spec. † Hort. kew.

yellow

yellow, ſcarcely longer than the calyx. Fruit twice as large as in G. urbanum[a].

Native of North America. Introduced in 1778, by Monſ. Thouin. It flowers in may and june[d].

3. Stalks from one to two feet high, nearly upright, ſomewhat flexuoſe, ſlightly angular, hairy, branched at top. Root-leaves varying, but moſt commonly pinnate, petioled with a ciliate ſheath, the end-leaflet large, divided ſometimes into three lobes, at others more deeply into three parts, the lateral leaflets few, ſmall, unequal; all deeply ſerrate, veined, and hairy: ſtem either divided almoſt to the baſe, or really ternate; accompanied with a large pair of roundiſh, toothed ſtipules, reſembling the leaflets. Peduncles ſingle, nearly upright, round, ſomewhat hairy, ſupporting one flower. Corolla ſmall, yellow, with very ſhort claws. Filaments yellowiſh, at firſt bent in, afterwards upright, half as long as the larger ſegments of the calyx: (not longer than the ſmaller ſegments. *Scop.*) Anthers roundiſh, yellow, turning brown: (having hairs about the edge, viſible only in a glaſs. *Scop.*) Germs hairy. Styles ſmooth, purple, fixed to the top of the germ, jointed in the middle, a little thickened at top[b]. Seeds about 110, ovate, of a pale ferruginous colour, covered with two ſkins; the outer leathery, terminated by the awn; the inner membranaceous, very thin, pale ſtraw-colour: embryo elliptic, ſlightly flatted, white; cotyledons oblong, thin; radicle ſhort, at bottom[c].

Common in moſt parts of Europe, in woods and hedges; flowering from may to ſeptember.

The roots have a mildly aſtringent aromatic taſte, ſomewhat like that of Cloves, whence this plant has the name of *Caryophyllata*. They ſhould be gathered in dry warm ſituations, for in ſhady, moiſt places they have little virtue. Gathered in the ſpring, and put freſh into ale, they give it a pleaſant flavour, and prevent its turning ſour. Infuſed in wine it is eſteemed a good ſtomachic; but in water Haller affirms it to have been attended with bad effects, when given in malignant fevers, producing delirium. Chewed in the mouth, the roots take off from a diſagreeable breath[e].

β. Obſerved by Dr. Liſter in Tedford wood on the Lincolnſhire wolds. Cultivated by Ray in his garden at Cambridge, from the neighbouring woods.

4. Stalk round, flexuoſe, upright, hirſute, a foot high or more, ſometimes, but ſeldom, a little branched at top. Branches alternate, very ſhort, ſomewhat tomentoſe. Leaves alternate, petioled, roundiſh, toothed, villoſe, ſoft, an inch in length. Petiole tomentoſe, a little ſhorter than the leaf. Stipules in pairs, leafy, ovate, gaſh-toothed, ſhorter than the petiole. Flowers terminating the ſtem and branches, ſolitary. Petals the length of the calyx. Seeds ovate, rough, with gray hairs. Awns ſubulate, hooked, reflex, ſmooth.—Native of Japan[b].

5. Root creeping, reddiſh, aſtringent, aromatic, ſmelling like cloves. Stem a foot high, upright, round and branched, bending at top, but becoming erect as the fruit ripens. Leaves lyrate, much larger than in *G. urbanum*, jagged, gaſh-ſerrate and hirſute. Stipules undivided, or jagged. Peduncles purpliſh, hirſute, with hairs terminating in a red globule, becoming leſs bent as the ſeeds ripen. Calyx cylindric, hirſute, with the ſame ſort of hairs as are on the peduncle, of a dull red colour. Petals upright, never expanding, the length of the calyx, purpliſh red and veined. Stamens near 100, or even more; filaments ſmooth, anthers yellow. Receptacle of the ſeeds oblong and peduncled; whereas that of *G. urbanum* is ovate and ſubſeſſile: the tip alſo of the awns is hairy, not naked as in the other[i].

Native of moſt countries of Europe, in moiſt paſtures and woods, indicating (according to Linneus) a barren ſoil, not fit for corn. Alſo in the Levant, and North America.—With us it is more common in the north, as on the water of Leith, near Edinburgh, and other places in Scotland on mooriſh grounds; Settle, Ingleton, &c. in Yorkſhire, and Lancaſhire, and by ſides of rivers and on mountains in many places of the northern counties. About Chevely and Wood-Dicton in Cambridgeſhire, where it was firſt found by Dr. Chevallier, the late maſter of St. John's College. In Wolverton wood near Lynn; at Marham near Swaffham, and near Norwich, in Norfolk. Near Sudbury, in a bog. Near Aſton in Warwickſhire. Alſo in Wales, by Mr. Thomas Glynn before 1633[k]. About Snowdon, &c.

It flowers from the end of may to autumn.

The powdered root is beneficial in diarrhœas and hæmorrhages, and is much uſed by the Canadians in the cure of tertian agues. It will cure malt-liquor of its ropyneſs.

This ſpecies varies with yellow flowers, and they frequently become double and proliferous.—Near Strickland in Weſtmoreland, obſerved by Mr. Lawſon; alſo at Brearcliff[l].

6. This ſeems to be a mule plant produced between the ſubſequent and foregoing ſpecies[m].

It grows much taller than *G. rivale*, and is in every reſpect a larger plant. The lower leaves are interruptedly pinnate, with three pairs of leaflets, beſides the ſmaller ones, and that at the end, which is very large. Calyx duſkier purple, tinged with green. Corolla yellow, only tinged with purple at the edge, about the ſame length with the calyx, having ſometimes more petals than five.

7. Root-leaves in a tuft, on petioles of different lengths; theſe are hairy, and have ſeveral pairs of leaflets on them, (five or more. *Haller.*) the loweſt very ſmall, the ſucceeding ones gradually larger, and the pair immediately under the great terminating leaflet much bigger than any of the reſt: the extreme leaflet is two or three inches in length and breadth, obſcurely lobed, gaſh-ſerrate, and veined. The leaves of the ſtem ſeſſile, ſolitary, alternate, trifid, the pinnas ſmaller and more crowded than in the others, ſeſſile and gaſh-ſerrate. Stem unbranched, from a ſpan to a foot and half in height. Flowers large, ſolitary, ſpreading, upright. Calyx wide, hairy, green. Petals yellow, almoſt ſaffron-coloured, emarginate, (ſometimes ſeven in number. *Haller.*) Anthers golden. Receptacle hairy[n].

In the mountains of Switzerland, Auſtria, Sileſia, Dauphiné, Arragon: Ray found it near the Great Chartreuſe in Dauphiné; and I gathered it on the Col. de Balme, in going from Chamouni to the Valais in 1779.—It flowers in june and july—with us in our gardens from may to ſeptember. Cultivated in 1597. Gerarde ſays it flouriſhes and increaſes infinitely in our London gardens.

β. Small Mountain Avens is made a diſtinct ſpecies by Mr. Miller,] who ſays that it is a very low plant, with flower-ſtalks about three inches long, bending on one ſide, each terminated by one bright yellow flower, about the ſame ſize with thoſe of the common ſort.

[Found on monte Baldo, &c.

8. On account of the calyx when ripe being bell-ſhaped; the corolla yellow and five-petalled; the receptacle elongated, the awns naked and jointed, this approaches nearer to a *Geum* than a *Dryas*. The leaves are pubeſcent on both ſides, blue underneath, and the whole appearance is that of a Geum. —The ripe calyx is cloſed by the five larger ſegments converging, and the briſtle-ſhaped, rigid, permanent filaments. Receptacle cylindric, ſlender, excavated, naked, a little ſhorter than the calyx. Seeds numerous, obovate, gibbous on one ſide, thence compreſſed into a ſtraight keel, ſhagreened on all ſides with raiſed dots, of a brown-ferruginous colour. Awn ſtraight, like a needle, twice as long as the ſeed, and inſerted into the top of it, ſmooth, and falling of itſelf when ripe[o].

[a] Jacquin. [b] Thunberg. [c] Hort. kew. [d] Gærtner. [e] Curtis, Withering, Haller, Linn. ſuec. Krocker. [f] Withering, Scopoli, Leers, Krocker. [g] Curt. & With. [h] Ger. emac. [i] Krocker. [k] Merret. [l] Gærtner. [m] Murr. in ſyſt.

Native of Siberia. It flowers in june.

Introduced in 1780, by Simon Pallas, M.D.[r]

9. Root large and woody. Stems ſome almoſt upright, flowering, hirſute, others procumbent, creeping; all round, having palmate, ſeſſile, alternate leaves, otherwiſe naked; the flowering ſtems are but little longer than the leaves, and bear uſually one flower, ſeldom two, and very ſeldom three. Moſt of the root-leaves are on petioles, rough with hairs: they are compoſed of two or three pairs of leaflets (four or five. *Haller*), with very ſmall ones interpoſed; the laſt pair larger than the other, the extreme leaflet very large, three or five-lobed: they are gaſh-ſerrate or toothed, hirſute, green, ſomewhat like the leaves of Parſley, ſmaller than in the other ſorts, and deeper cut. Flower much larger than in the *montanum*: calyx green, with the ſegments often reddiſh; they are larger than in the *montanum*, and lanceolate: petals yellow, emarginate, marked with lines, much larger than the calyx; the whole corolla ſometimes two inches in diameter. Styles ſilky. Receptacle villoſe[s].

Native of Switzerland, Auſtria, Sileſia, Savoy and Piedmont; flowering in june and july.—Introduced in 1775, by Doctors Pitcairn and Fothergill[t].]

PROPAGATION AND CULTURE.

The third ſort being common in a wild ſtate, is admitted only into botanic gardens. They are all hardy plants, which require a ſhady ſituation, but will thrive in any ſoil. They may eaſily be propagated by ſeeds, which ſhould be ſown in autumn; for when they are ſown in the ſpring, they do not grow the ſame year.

[GEUM. See *Dryas* and *Saxifraga*.

DESCRIPTIONS, *&c.*

1. Stem ſlender, woody, branching, near three feet high. Leaves oval, ſharply indented, light green, on ſhort foot-ſtalks. Flowers diſtant, ſeſſile, in a looſe ſpike, on ſlender, naked, axillary peduncles, ſix or ſeven inches in length. Corollas ſmall, bright blue. Seeds two, terminated by ſhort awns, and incloſed in the calyx.

[It is an annual plant, and native of the Weſt-Indies, Antigua, Curaçoa, &c'.] The ſeeds were ſent to Mr. Miller from La Vera Cruz, by Dr. Houſtoun.

[2. This alſo is an annual plant, about a foot and half in height. Stem ſtrong, ſtraight, a little woody. Leaves rounded or ſubovate, deeply toothed, having ſhort hairs on both ſurfaces. Petioles three or four lines in length. Spikes axillary, oppoſite. Flowers ſolitary, few, alternate, pedicelled, with a ſmall, linear bracte at the baſe of each pedicel. Corolla blue. Fruit black, incloſed within the calyx; nut cloſe and woody, four-celled or five-celled, each cell having a ſmall kernel in it. Native of Guiana, and the iſland of Cayenne'.

SPECIES.

Ginannia guianenſis.
Paloue guianenſis. *Aubl. guian.* 365. *t.* 141.

DESCRIPTION, *&c.*

This is a ſhrub growing to the height of fifteen feet, beginning to be branched at one or two feet from the ground. Leaves alternate, entire, ſmooth, ovate-oblong, acuminate, ſubſeſſile; the largeſt ſix inches long, and two inches and a half wide. Stipules minute, in pairs, at the baſe of the petioles. Flowers terminating, three or four together, on a ſhort peduncle, on which are four or five ſoft green ſcales, or bractes.

Native of the foreſts of Guiana, flowering in february, and fruiting in may[v].

Juſſieu doubts whether the corolla may not have five petals, two of which drop off quickly; and alſo, whether there may not be a tenth filament, which is barren?

After all, may not this ſhrub be a ſpecies of Brownea?

Gingo du Japon. *Lamarck. encycl.* 712.

DESCRIPTION, *&c.*

This tree grows to a prodigious size, with a trunk frequently as thick as the largest oak; the branches are alternate and spreading. Leaves alternate, petioled, wedge-shaped, rounded on the upper edge, where they are slightly gashed or notched unequally, with a large sinus in the middle, dividing them into two lobes: they come out in bundles at the knots or tubercles of the branches, are smooth, and finely striated by numerous parallel forked veins, but they have neither rib nor nerve, and are not much unlike the leaves of Maidenhair; they are from an inch and half to three inches in width; and the petioles are about two inches long, slightly channelled, pubescent at the base above, with the edges of the leaf running down the top [a].

Of the fructification we yet know very little with certainty. The flowers are male and female separate, probably on different trees. The male flowers were produced last year (1795) in the royal botanic garden at Kew, but in a state not sufficiently perfect to determine the character absolutely. They come out in april, before the leaves, and from the same bud with them, towards the ends of the branches; on aments or katkins, as Kæmpfer describes them, pendant and longish, abounding in pollen.—The female flowers are probably solitary or few in number in the axils of the leaves, Kæmpfer having assigned this situation to the fruits, which he says grow on a thick fleshy peduncle an inch in length, and having figured them single: he describes them as round or oblong, of the appearance and size of a Damascene Plum or Damson, with a warted surface becoming yellow as the fruit ripens, and a fleshy, juicy, white pulp, adhering very closely to the nut, which resembles that of the Pistachia, but is almost double the size, and more of the form of an Apricot stone; the shell is woody, thin, brittle and whitish, and the kernel is white, rather firm, sweet, with a mixture of austerity, or bitterness, when raw, but is agreeable when roasted gently on the coals, before the skin is taken off. In this state it is supposed to help digestion.

Native of Japan and China. Cultivated in 1758 by Mr. James Gordon [b], who first sent the tree to Linneus [c]. See SALISBURIA.

Lin. spec. 642. *Syst.* 447. *Reich.* 2. 429. *Jacqu. amer.* 148. *t.* 91. *pict.* 1. 137.

DESCRIPTION, *&c.*

An elegant shrub, with the appearance of Myrtle. Leaves opposite. Peduncles axillary and terminating, bearing one flower [a].

It grows upright, to the height of three or four feet, and divides into smooth branches, round, except that they are compressed at the origin of the twigs and leaves, all woody. Leaves lanceolate, acute, quite entire, smooth, spreading, an inch and half long, on very short petioles. Peduncles slender, spreading, solitary, an inch in length. Flowers handsome, almost an inch in diameter, without any scent. Calyx red; corolla blue; capsule dark-red, outwardly resembling a berry [b].

Native of Cuba, by river sides, and called there Rosa del rio, or river Rose.

GINSENG. See *Panax*.

Koelreutera molluginoides. *Comm. gott. nov.* 3. 67. *t.* 1. *f.* 1.

DESCRIPTION, *&c.*

Stalks herbaceous, decumbent, smooth, round, scored with a line on the upper side, a foot long, with remote joints. Branches of the base alternate. The herb resembles that of *Silecebrum spicoideum*. Leaves opposite, petioled, elliptic-lanceolate, quite entire, blunt, smooth and even, spreading. Peduncles axillary, solitary, round, naked. Umbel simple, many-flowered. Flowers green on the outside, white within, hanging down, except on the day of flowering [a].—The lower branches are trichotomous, the rest flexuosely and alternately dichotomous. The leaves in the trichotomies opposite, the rest alternate; all flat and granulated. Most of the flowers axillary, on one-flowered peduncles: the segments of the calyx with scattered hairs on the inside. Capsules or seeds black [b].

It is an annual plant, native of the East-Indies; flowering here in june.—Introduced in 1783, by John Earl of Bute [c].

DESCRIPTION, *&c.*

A large tree reſembling *Laurus Camphora*, or the Camphor-tree. Leaves alternate, petioled, ovate-lanceolate, quite entire, ſmooth, acuminate, ſubtomentoſe underneath, even nevertheleſs, and glaucous. Flowers white, in little axillary balls, forming a ſort of raceme, leafleſs, and much ſhorter than the leaves. Calyxes the colour of Elæagnus.—Native of the Eaſt-Indies*.

The wood is very light and pale-coloured; being not liable to rot, or to be attacked by inſects, it is much uſed in building both houſes and ſhips.

Gladiolo accedens. See *Xyris*.

Gladiolo ſimilis. See *Anthobolyza*.]

Stem round, tube of the corolla very long, spathes and leaves linear, smooth.

28. Gladiolus spathaceus.
Lin. syst. 87. *suppl.* 96. *Thunb. diss. n.* 25.
Stem branched, flowers in imbricate spikes, spathes membranaceous, ovated, leaves plaited.

29. Gladiolus setifolius.
Lin. syst 87. *suppl.* 96. *Thunb. diss. n.* 19.
Stem branched, corolla ringent, the lowest leaf filiform-setaceous.

30. Gladiolus Cardinalis. *Superb Corn-flag.*
Curtis magaz. t. 135.
Leaves sword-shaped, many-nerved; flowers directed the same way, many on a stem: corolla upright, with a bell-shaped border.

DESCRIPTIONS, &c.

These are herbaceous perennial plants, with a tuberous coated root; a simple stalk; the flowers specious, in spikes, with a spathe to each flower. The germination as in the *Ixia*, with the lobe absolutely sessile [a].] Most of them, except the first, known only to modern times, and natives of the Cape.

1. Root round, compressed, yellowish, covered with a brown furrowed skin; hence spring two sword-shaped leaves, embracing each other at the base, and between them rises the flower-stalk, growing near two feet high, having one or two narrow leaves embracing it like a sheath, and terminated by five or six purple flowers, one above another at some distance, ranged on the same side of the stalk. The spathe covers the flower-bud before it expands, but splits open lengthwise when it opens, and shrivels up to a dry skin, remaining about the seed-vessel till the seeds are ripe. The three upper segments of the corolla are near together, the lower one turns down, and the two side segments spread open at top, but are curved downwards at bottom.

[The three lower segments are marked with a white spot. Seeds imbricate, as far as eight in one cell.

It was cultivated by Gerarde in his garden in 1596 [b], and it was even then very common.

He gives the names not only of Corn-flag, but Corn-sedge, and Corn-Gladin. Johnson adds that of Sword-flag.

Mr. Miller makes three species of this: 1. the common sort, described above; *G. flor. uno versa dispositis* of C. Bauh.—with the flowers disposed on one side the stalk, varying with white and flesh-coloured flowers. This Gerarde calls Italian Corn-flag.—2. the Italian (G. Italicus.)—*utrinque floridus* of C. Bauh.—with flowers on each side the stalk; of which he says there is also a variety with white flowers.—This Gerarde and Parkinson figure under the name of French Corn flag.—3. The great Corn-flag of Byzantium (G. Byzantinus)], which has larger roots, but of the same form; the leaves also are much broader, and larger, with deeper channels. The flower-stalks rise higher, the flowers, are much larger, of a deeper red colour, and the sheaths are longer. It makes a fine appearance when in flower, and is worthy of a place in every good garden; the rather, because the roots do not increase so fast as to be troublesome.

[Parkinson, besides the French, Italian and Byzantine Corn-flags, has three varieties—the bluish, white, and small purple. He observes that Gerarde mistook the French for the Italian: and that John Tradescante assured him, that he saw many acres of ground in Barbary spread over with them.

2. Flowers small, all directed one way, and imbricate. Native of Russia [c].

3. Stem a span high, thickish, flexuose between the flowers. Leaves streaked, smooth, blunish, those next the flowers shorter, in a double row. Upper lip of the corolla sickle-shaped, narrow; side petals or wings of the same length, rhomb-shaped, very broad; lower lip three-parted, the leaflets ovate and equal. Native of the Cape of Good Hope [d].

4. Leaves a span long and more. Stem round, villose, a finger's length. Flowers sessile, mostly on one side. Bractes three at the base of each germ, hirsute, acuminate; the outer an inch and half long; the inner half that length. Tube of the corolla filiform-cylindric, twice as long as the spathes, violet, fading to white: border funnel-shaped, six-parted; divisions lanceolate, acuminate, a quarter only of the length of the tube, straw-coloured; the three upper ones beyond the middle reflex, with a forked red spot at the base, and an angular very deep red spot in the middle of the side ones; the three lower divisions have no spot. Stigmas somewhat wedge-shaped, villose above. Native of the Cape of Good Hope, where it was found by Thunberg and Masson. It flowers in june; and was introduced in 1774 [e].

5. Leaves plaited at the nerves. Flowers two or three, violet, fading to white. Bractes in threes, narrow, the outer one largest [f].]

Root round, compressed, about the size of a small Spring Crocus; the skin red: from this arise five or six sword-shaped, hairy leaves, from two to four inches long, and one third of an inch broad, dark green, sitting close at the base, but spreading upwards, like the sticks of a fan: between these rises the flower-stalk, six or eight inches in length, naked to the top, terminated by a spike of deep blue flowers: corolla divided to the base into six obtuse parts, equal in size and position. Style the length of the stamens dividing into three parts, each crowned by a roundish stigma. It flowers in may, and the seeds ripen in july; soon after which the stalk and leaves decay to the root [g].

[a] Jussieu.
[b] Hort. kew.
[c] Linn. spec.
[d] Linn. amœn.
[e] Hort. kew.
[f] Linn. spec.
[g] Mill. ic.

Cultivated in 1757, by Mr. Miller [b]; who raiſed it from ſeeds which were ſent him from the Cape of Good Hope.

[6. This varies with a deep blue corolla, the tube and the baſe of the ſegments a very dark purple: and with a pale purple corolla, the tube blue. It was found at the Cape by Mr. Frances Maſſon, and introduced in 1774. It flowers in june [l].]

7. From the root come out two or three narrow leaves, a foot and half long, having a longitudinal furrow in the middle, and ending in acute points; they are of a deep green, and ſtand erect. Between theſe ariſes a ſlender taper ſtalk, about the ſame length as the leaves, having one or two ſhort acute-pointed leaves on the lower part, embracing the ſtalk at their baſe. Flower alternate, diſtant. Tube of the corolla curved downward, and not ſo long as in moſt of the other ſorts; ſegment acute, and nearly equal; pale yellow or ſulphur colour. Filaments long, erect; anthers pyramidal, dirty white. Style ſlender, terminated by a trifid, reflex ſtigma. It flowers the end of may, and the ſeeds ripen about ſix weeks after [k].

[Linneus gave the name of *triſtis* to this ſpecies, from the gloomy colour of its flowers. They are very frequently of a pale yellow or ſulphur colour (as deſcribed above) ſhaded in particular parts with very fine pencilings, eſpecially on the under ſide [l]: but they vary much with different ſhades of white and green, yellow, fleſh-coloured, blue, purple and violet. Thunberg has diſtinguiſhed ſixteen of theſe varieties. It is commonly ſaid to produce only two flowers on a ſtem, but there are frequently more. They generally give forth a moſt agreeable fragrance in their expanſion.

The leaves very characteriſtically diſtinguiſh this ſpecies [m]: they are alternately ſheathing, linear, acute, ſtriated, ſmooth, quite entire, two or three in number, the upper ones gradually ſhorter; the loweſt is thickiſh, ſcored with a deep groove within the edge, the reſt reſemble the ſpathes, and are convoluted, but they are longer [n].

Native of the Cape of Good Hope, and cultivated in 1745, by Mr. Miller [o].

8. Stalk a foot and half high, and round. Leaves longer than the ſtalk. Flowers ſweet: tube ſubcylindric, little more than half an inch in length, whitiſh; border ſubcampanulate, ſubringent; the three upper diviſions obovate-oblong, twice as long as the tube, pale violet; the three lower narrower, that in the middle the ſame length with the three upper ones, yellow below the middle; the ſide ones ſhorter, yellow in the middle.—Native of the Cape. Mr. Francis Maſſon. Introduced 1774. It flowers in april and may [p].

9. Tube of the corolla narrow, compreſſed, little bent, an inch and half in length, pale red. Upper diviſion of the border oblong, acute, concave in the middle, and there dilated, above the middle reflex, whitiſh fleſh-colour, the ſame length as the tube; the two ſide diviſions oblong-lanceolate, ſpreading, reflex at the tip, fleſh-coloured, a little ſhorter than the upper one; the three lower diviſions linear-lanceolate, from erect ſpreading, above the middle a little reflex, whitiſh fleſh-colour, with a red tranſverſe ſpot in the middle, a little ſhorter than the upper ones: the middle ones ſharper than the others. Filaments white, half the length of the corolla; anthers oblong, linear, erect, blue. Style white, longer than the filaments: ſtigmas three, patulous, dilated at tip into two-lobed laminas villoſe at the edge.—Native of the Cape of Good Hope. Mr. Francis Maſſon. Introduced 1774. It flowers in june [q].

10. This is of the ſame ſtature with the common ſort. Stalk a foot and half in height. Leaves ſtreaked. Flowers alternate, in a double row. Proper ſpathes two-leaved, the inner leaf ſmalleſt. Tube of the corolla long, filiform: the ſix parts of the border nearly equal, in form of a Lily, waved, eſpecially the alternate ones.—Intermediate between this genus and Ixia.—Native of the Cape. See n. 14.

11. This differs from the foregoing, in the petals not being waved, and being leſs acuminate; the tube of the corolla not filiform, lax or pendulous: in other reſpects this is very like it [r].]

Stalk ſlender; has more leaves upon it than *G. triſtis*. The flowers are ranged on one ſide the ſtalk towards the top, and ſtand pretty far aſunder. Corolla curved; ſegments of the border almoſt equal, ending in blunt points; the lower ſegments turning downwards, the upper erect, and ſpreading open: the colour pale-blueiſh, approaching to white, each ſegment marked with a broad purple divided line along the middle. Anthers purpliſh, oblong, erect. Style of the ſame length with the ſtamens, crowned by a trifid reflex ſtyle. The flowers have an agreeable odour; they appear at the end of may, and the ſeeds ripen in july. It was raiſed in the Chelſea garden, from ſeeds which came from the Cape of Good Hope, and flowered there before the year 1760 [s].

[12. Scape ſimple, round, ſheathed, erect, a ſpan high. Leaves four, alternate, linear, ſmooth, the lower gradually ſhorter. Flowers diſtich, imbricate, blue, about twelve pairs in a ſpike of an inch in length. It differs from the next ſpecies in having larger flowers, on a ſhorter ſpike, but broader and ovate; and a ſimple ſcape [t].

13. The ſpike covered as in Plantain, with very numerous ſmall flowers; but in a double row [u]. It varies with the ſcape ſimple and branched, with corollas white and blue [x]. This, and n. 12. are natives of the Cape.

14. Scape ſimple, or but little branched, ſheathed, round, ſtriated, ſmooth, flexuoſe-erect, a foot high. Leaves from long ſheaths, enſiform, marked with white elevated ſtreaks, entire, ſmooth, ſhorter than the ſcape, the upper ones gradually ſmaller. Flowers all on the ſame ſide aſcending, on one or two ſpikes, a hand in length. Rachis angular, flexuoſe, twiſted, ſmooth. Spathes the length of the tube of the corolla, ſhorter than the branches, green. Segments of the border of the corolla uſually waved.—The ſame, according to Thunberg, with n. 10 [y].

Cultivated in 1757, by Mr. Miller [z].

15. This differs from the next ſpecies in having the bractes acuminate, the whole corolla intenſely yellow, and the leaves a little broader. It was found near the Cape, by Mr. William Patterſon; and was introduced in 1780, by the Counteſs of Strathmore. It flowers in february and march [a].

16. Leaves ſmooth, more than a ſpan in length. Stalk roundiſh, a little ſhorter than the leaves, ſometimes branched. Bractes ſhort, ovate, obtuſe, ſometimes gaſhed at the tip, membranaceous. Corollas pale tawny: tube funnel-ſhaped, leſs than an inch in length; ſegments of the border oblong-ovate, obtuſe, ſometimes obſcurely emarginate, ſhorter than the tube; the three upper ones having in the chaps a yellow ſpot with a border of red round it, and three flat, obtuſe, yellow laminas, a line and half in diameter. Native of the Cape. Mr. Francis Maſſon. Introduced in 1774. It flowers in may [b].

18. A very large plant, with blue flowers [c]. This and the foregoing are natives of the Cape. See *Morœa*.

19. Leaves long. Stem round, with one or two crenate, waved leaves on it. Flowers numerous, upright. Glumes obtuſe, with a ſcarioſe, toothletted, red margin. Tube of the corolla twice as long as the border.—It is wholly different from *Ixia criſpa*, in having lanceolate leaves, even on the ſtem; the tube of the corolla eight times as long as the glumes, and the petals lanceolate: whereas that has linear leaves, and a leafleſs ſtalk; the tube of the corolla hardly longer than the glume, and the petals obovate. This alſo is two feet high, and that only about four inches.

Found at the Cape by Sparrmann.

[b] Hort. kew. [l] Ibid. [q] Mill. fig. [s] Thunberg.
[k] Curtis. [m] Ibid. [r] Thunberg. [t] Ibid.
[n] Hort. kew. [p] Ibid. [u] Ibid. [x] Ibid.
[y] Linn. ſpec.

20. Stem a hand only in height, filiform, ſmooth, with one or two patulous branchlets. Leaves ſmooth and even, ſhorter by half than the ſtem. Flowers alternate, ſeſſile. Glumes ovate, entire. Corolla violet-coloured, with a filiform tube longer than the border. Found at the Cape by Thunberg.

21. Leaves ſtreaked, ſhorter than the ſtem; thoſe on the branches ſhort, but not narrower, decurrent, with a curled keel. Flowers alternate, at the tips of the branches. Spathes very obtuſe, purple at the edge. Tube of the corolla three or four times as long as the border.—This is allied to *Ixia corymboſa*, and reſembles it in its angular ſtalk; but differs both from that and the *palmaris* in the long, filiform tube of the corolla.

22. Stem more than a foot high, round, ſmooth and even, with a few flowering branches. Leaves graſſy, almoſt the length of the ſtem, ſmooth and even, nerved, lax. Flowers few at the ends of the ſtem and branches. Spathes ovate, acuminate. Corollas whitiſh, with a violet-coloured baſe, ſmall, without a tube, ſix-parted[4].

23. Leaves a foot long, ſword-ſhaped, ſmooth and even, with the edges three times as thick as the reſt. Stems the thickneſs of a gooſe-quill. Spike very long, ſlightly flexuoſe between the flowers. Spathes diſtant, the length of the bractes, which are often jagged at the tip. Tube of the corolla twice as long as the ſpathes: ſegments of the border nearly equal, oblong, elliptic, purple.

24. Root-leaves narrow, linear, not above a line in breadth, but nearly the length of the ſtem, ſmooth and even. Stem round, leafleſs. Spike oblong, with the flowers rather remote. Upper lip or helmet of the corolla three-parted; the middle ſegment arched or bowed in, channelled, linear, ovate at the tip; lateral ſegments ſpreading, divaricate, bowed back, obovate, longer than the claw: lower lip three-parted, equal; ſegments obovate, purple, with a long claw. The ſtamens are under the middle ſegment of the upper lip.—This, with the three foregoing, was found at the Cape by Sparrmann.

25. Scape compreſſed, ſtriated, flexuoſe, ſmooth, a hand in height. One or two leaves, obverſely ſtem-claſping, ovate-lanceolate, ſickled, bluntiſh, entire, ſtriated, ſmooth. Spathes green, obtuſe, much ſhorter than the tube. Corolla blue, with a ſpreading border. Allied to Ixia exciſa:—and perhaps rather a ſpecies of that genus.

26. Scape round, flexuoſe, erect, ſmooth, a foot high. Leaves none in flowering time. Spathes oblong-lanceolate, acuminate, ſmooth, ſhorter than the tube of the corolla. Spike ovate, four or five-flowered. Corolla whitiſh fleſh-colour, with a tube double the length of the ſpathe, and a ringent border.

27. Scape round, ſimple and many-ſpiked, erect, ſmooth, a foot high and more. Leaves three or four, enſiform, nerved, ſmooth, ſhorter than the ſcape. Flowers alternate, pale fleſh-colour, very many, cloſe. Bractes membranaceous, ſtriated, very ſhort. Tube of the corolla from an inch to two inches in length, widening at top, curved, erect. It has the appearance of an Ixia, but the curved tube and ſituation of the border ſeparate it from that genus.

28. Scape ſheathed, a ſpan high, terminated by ſeveral ſpikes. Leaves enſiform, nerved, villoſe, the length of the ſcape. Flowers whitiſh, with the tube of the corolla many times longer than the ſpathes. Spikes imbricate, a finger's length. Spathes membranaceous, often torn, awned. It reſembles G. tubiflorus and plicatus, but differs in the ſpathes.

29. Scape many-ſpiked, very ſeldom ſimple, flexuoſe-erect, ſmooth, a hand high, with round erect branches. Leaves about three, linear-briſtle-ſhaped, gradually ſhorter, the loweſt very long, equalling the ſcape. Flowers alternate, white, ringent, with the tube ſcarcely longer than the ſpathes. Theſe were all found at the Cape of Good Hope by Thunberg[5].

30. Flowers fine ſcarlet, with large white ſome-

[4] Linn. Suppl. [5] Thunb. diſſ.

what rhomboidal ſpots on ſeveral of the lowermoſt diviſions of the corolla: ſtrong plants will throw up a ſtem three or four feet high, dividing at top into ſeveral branches. It flowers with us in july and auguſt; and is moſt probably a native of the Cape. Introduced from Holland a few years ſince, by Mr. Græffer, now gardener to the King of Naples. It firſt flowered with Meſſrs. Lewis and Mackie, nurſery-men at Kingſland, and in 1790 at Meſſrs. Grimwood's and Co. at Kenſington[1].]

PROPAGATION AND CULTURE.

1. The firſt requires no care; for when it is once planted in a garden, it will multiply too faſt, ſo as to become a diſagreeable weed. The Byzantine Corn-flag has now, therefore, generally taken its place. This is propagated by offſets which are ſent off from the roots in the ſame manner as Tulips. The roots may be taken out of the ground the end of july, when their ſtalks decay, and may be kept out of the ground till the end of ſeptember, or the beginning of october, at which time they ſhould be planted in the borders of the flower-garden, where they will thrive in any ſituation, and being intermixed with other flowers of the ſame growth, they will add to the variety.

The Cape ſorts may be increaſed by offſets, which ſhould be planted in a warm border of kitchen-garden earth, and in winter they ſhould be covered with glaſſes or mats to guard them from froſt; for I have with a ſlight ſhelter preſerved thoſe which were in pots under a common frame, and ſome which were planted in the full ground, when the froſt has not been ſevere; and I have always found that thoſe plants which were hardily treated, grew much ſtronger than thoſe which were placed in a moderate degree of warmth; ſo that where there is a conveniency of covering a warm border with glaſſes in the winter, if theſe roots are planted in the full ground, where they may be protected from froſt, there will be a greater probability of their flowering than in any other method of culture.

And alſo by ſeeds, which are frequently perfected in England; theſe ſhould be ſown at the end of auguſt, in pots filled with light earth, and placed in a ſhady ſituation till the middle of ſeptember; then the pots ſhould be removed where they may have the ſun great part of the day, and in october they muſt be placed under a hot-bed frame, where they may be protected from froſt and great rains, but enjoy the free air in mild weather. In the ſpring the young plants will appear, when they will require a little water once in eight or ten days, but it ſhould be given them ſparingly, for too much wet will rot theſe tender bulbs. In may, when the danger of froſt is over, the pots ſhould be removed to a ſheltered ſituation, where they have the morning ſun till noon; and, if the ſeaſon proves dry, they muſt be now and then refreſhed with water. Towards the latter end of june, the leaves of theſe plants will decay; then the roots ſhould be taken up, and may be mixed with ſand, and kept in a dry room till the end of auguſt, when they ſhould be planted again; and as the roots are ſmall, four or five may be planted in each half-penny pot, filled with light earth; theſe ſhould be placed where they may have only the forenoon ſun, till the middle of ſeptember, when they ſhould have a warmer ſituation; and in october they muſt be placed under a hot-bed frame as before, and treated in the ſame way during the winter ſeaſon; and in the ſpring they muſt be placed in the open air till their leaves decay, when they may be again taken out of the ground, and treated in the ſame manner as before; but as the roots will have grown to a larger ſize when they are planted again, they ſhould each have a ſeparate half-penny pot, becauſe now they will be large enough to flower, and may be treated as the old roots.

Alfine bifolia, fr. coriandri, rad. geniculata. *Loefel. pruff.* 13. *t.* 3.

DESCRIPTION, &c.

Root perennial, creeping. Stems trailing, jointed; branched a little. Leaves feſſile, oval-oblong, or oval-lanceolate, ſucculent; oppoſite at bottom but among the flowers alternate. Flowers almoſt feſſile, axillary, ſolitary, from about the middle of the ſtem, purple, greeniſh white, white or ſtriped [a].

On the ſea-coaſt, and on ſalt marſhes at a diſtance from the ſea. Even about Upſal, which is very far from the ſea [b]—It is a pretty little plant, enlivening large tracts of the dreary ſituations where it is found. The whole plant is ſucculent and ſalt to the taſte [c]. Cows eat it. It flowers in June and continues the reſt of the ſummer.] It is ſeldom cultivated in gardens.

Leaves kidney-ſhaped, crenate or ſcalloped.

DESCRIPTION, &c.

Root perennial, ſending out trailing four-cornered ſhoots, producing roots at the joints, and ſpreading wide. The flowering ſtalks ſpring from the joints, which are woolly; theſe are upright but weak, ſquare, hirſute with hairs turning downward, from four to ſix inches high. Leaves oppoſite, wrinkled, ſomewhat hairy, on grooved petioles, as long as the leaves; they are beſet underneath with hollow dots, in which are glands ſecreting an eſſential oil, and above with, little eminencies, but which do not ſecrete any odoriferous oil, ſo that this ſurface being rubbed gives out no peculiar ſcent, whereas the under ſurface affords a pleaſant reviving ſmell [d]. Peduncles axillary, oppoſite, ſhort, branched, ſupporting from three to five flowers. There is a pair of floral leaves at the branching of the peduncle, and another pair under each of the lateral flowers, they are ſubulate, or ſetaceous, and very ſmall, the middle flower has none. Calyx hairy, ſtreaked, with the teeth nearly equal. Corolla blue (ſometimes varying to white) the large middle ſegment of the lower lip marked with purple ſpots of a deeper colour, and hairy at the baſe. Stamens ſometimes in the ſpring imperfect, with filaments only half the uſual length, terminated by a reddiſh blunt point, or ſometimes by effete anthers: when perfect, the anthers, after burſting, form a croſs, or the ſhape of the letter X [e].

It is very ſtrange that Scopoli ſhould deny this character, no leſs evident than beautiful and ſingular. We can account for it only by ſuppoſing, that he muſt have examined the flowers when they were in an imperfect ſtate, which they frequently are early in the ſpring.

The leaves are often deformed with red hairy tumours, which are the galls of the Cynips Glechomæ [f]. It gradually expels plants which grow near it, and thus impoveriſhes paſtures [g]. The leaves were formerly thrown into the vat with ale to clarify it, and to give it a flavour. This was called Gill-ale; Ground-Ivy being named Gill or Gill-creep-by-ground, in ſome places. From this uſe of the plant, and the form of its leaves, it has alſo the names of Ale-hoof and Ton-hoof [h], &c. but it has gradually grown into diſuſe ſince the introduction of Hops. Cattle ſeem rarely to touch it; according to Linnæus, ſheep eat it, horſes are not fond of it, and it is refuſed by cows, goats, and ſwine. It is ſaid to be injurious to horſes, if they eat much of it. The expreſſed juice, mixed with a little wine, and applied morning and evening, deſtroys the white ſpecks upon horſes eyes [i].

Ground-Ivy has a peculiar ſtrong ſmell, and a bitteriſh taſte, ſomewhat aromatic. It was formerly

[d] Withering.

[e] Curtis, Lyons M. S. Withering and Stokes in Withering.

[f] Linn. and Lightf. [g] Linn. ſuec. [h] Ray and Withering.

[i] Linn. ſuec. from Loefel.

in conſiderable credit for pectoral, detergent, aperient, diuretic, corroborant, and other qualities; and was recommended particularly in pulmonary and nephritic complaints. In obſtinate coughs it is ſtill a favourite remedy with the common people; but it is little preſcribed by medical practitioners, and is wholly diſcarded from the materia medica of the London College. Mr. Ray gives a remarkable inſtance of its efficacy in removing a violent and inveterate head-ach by drawing the juice of the plant up the noſtrils: but Dr. Cullen will not allow it to act any otherwiſe than as an errhine. He alſo thinks the uſe of it in ale to be frivolous; and affirms, that in many caſes where he had ſeen it employed, there was no evidence either of its diuretic or pectoral effects[s].

It is moſt uſually taken in form of an infuſion or tea; the expreſſed juice is alſo uſed with honey in coughs: a conſerve or ſyrup is alſo made with it. The diſtilled water cannot be of any avail. Some foreign phyſicians ſeem to have a better opinion of this herb than ours.

It is ſo common under hedges, on banks, in woods, and ſometimes in dry paſtures, that it is never cultivated in gardens. It varies in ſize, as well as the degree of colour in the flower, according to its ſituation. The flowers appear in april, may, and june. Thunberg obſerved it in Japan.

A plant ſo common, and ſo much eſteemed by the multitude, has of courſe many names. To ſuch as are given above we may add thoſe of Cat's-foot, Hay maids, and Robin-run-in-the-hedge. In German it is *Gundelreben, Gundermann, Grundermann, Gundelrab, Gundrebe, Grundrebe, Gunderlunze, Donnerrebe, Erdepheu, Erdenkranzlein, Meerwurzel*; in Dutch *Aardveil, Hondſdraf, Onderhave*; in Daniſh *Vedbende*; in Swediſh *Jordrefvot*; in Italian *Ellera terreſtre*; in Spaniſh *Hiedra terreſtre*.

DESCRIPTION, *&c.*

1. α. This tree is common in moſt parts of North America, where it is known by the name of Honey Locuſt; it is called by the gardeners here Three-thorned Acacia. It riſes with an erect trunk to the height of thirty or forty feet, and is armed with long ſpines, three or four inches long, which have two or three ſmaller ones coming out from the ſide, and are frequently produced in cluſters at the knots of the ſtem. Leaves bipinnate, compoſed of ten pairs of leaflets, of a lucid green and ſeſſile. The flowers come out from the ſide of the young branches, and being of an herbaceous colour, make no figure. Legume near a foot and half long, and two inches broad. Seeds ſmooth, ſurrounded by a ſweet pulp.

The leaves ſeldom come out till june in this country, and the flowers not till the end of july. This tree does not produce any flowers till it is of a large ſize. There was one in the Biſhop of London's garden at Fulham, which produced pods in the year 1728, that came to their full ſize, but the ſeeds did not ripen.

[It appears from Plukenet that it was cultivated by Biſhop Compton in 1700[t].]

β. This has much the appearance of the other, but has fewer ſpines. The leaves are ſmaller, and the pods are oval, containing but one ſeed. It was diſcovered by Mr. Cateſby in Carolina.

[Legume coriaceous, thin, very much compreſſed, pedicelled, unequally elliptic, ſcarcely opening ſpontaneouſly, the valves being connected outwardly by a thin cellular ſubſtance. It contains only one ſeed, which is elliptic, flattiſh on both ſides, hard, very ſmooth, ſhining, of a yellowiſh bay colour; and thus differing much from the firſt, which has a very large, broad legume, very much compreſſed, with ſeveral tranſverſe partitions, and filled with pulp[u].]

PROPAGATION AND CULTURE.

Theſe trees are propagated by ſeeds, which muſt be procured from America; thoſe of the firſt are annually ſent to England in plenty, by the title of Locuſt, or Honey Locuſt, to diſtinguiſh it from the falſe Acacia, which is frequently called Locuſt-tree in America; theſe ſeeds may be ſown upon a bed of light earth in the ſpring, burying them half an inch deep; and if the ſpring ſhould prove dry, they muſt be frequently watered, otherwiſe the plants will not come up the firſt year, for ſometimes the ſeeds remain two years in the ground before they come up; therefore thoſe who are deſirous to ſave time, ſhould ſow the ſeeds as ſoon as they arrive, and plunge the pots into a moderate hot-bed, obſerving to water them frequently, by this method moſt of the plants will come up the ſame ſeaſon, but theſe ſhould be gradually inured to bear the open air, for if they are continued in the

[t] Hort. kew. [u] Gærtner.

hot-bed, they will draw up weak: during the ſummer ſeaſon, thoſe plants in pots will require frequent waterings, but thoſe in the full ground will not dry ſo faſt, therefore need no water, unleſs the ſeaſon ſhould prove very dry. In autumn, thoſe in the pots ſhould be placed under a hot-bed frame to protect them from froſt, for theſe young plants generally keep growing late in the ſummer, and the upper part of their ſhoots being tender, the early froſts of the autumn often kill the ends of them, if they are not protected, and this frequently occaſions great part of the ſhoots decaying in winter; for which reaſon thoſe ſhoots in the full ground ſhould be covered with mats in autumn, on the firſt appearance of froſt; for a ſmall froſt in autumn will do more miſchief to theſe young ſhoots which are full of ſap, than ſevere froſt when the ſhoots are hardened.

The following ſpring they may be tranſplanted into nurſery-beds, at a foot diſtance row from row, and ſix inches aſunder in the rows: but this ſhould not be performed till april, after the danger of hard froſt is over; for as the plants do not put out their leaves till very late, there will be no hazard in removing them any time before may. If the ſeaſon ſhould prove dry, they muſt be watered; and if the ſurface of the beds is covered with moſs, or mulch, to prevent the earth from drying, it will be of great ſervice to the plants. In theſe beds the plants may remain two years, during which time they muſt be conſtantly kept clean from weeds; and in the winter there ſhould be ſome rotten tan, or rather mulch, ſpread over the ſurface of the ground to keep out the froſt. If the plants thrive well, they will be fit to tranſplant to the places where they are to remain after two years growth, for they do not bear removing when large; the beſt ſeaſon for tranſplanting theſe trees, is late in the ſpring; they thrive beſt in a light deep ſoil, for in ſtrong ſhallow ground they become moſſy, and never grow large; they ſhould alſo have a ſheltered ſituation, for when they are much expoſed to winds, their branches are frequently broken in the ſummer ſeaſon, when they are fully clothed with leaves.

[This being an elegant tree, it ſhould appear ſingly in the openings of plantations, provided it be well ſheltered from cold winds, but it is not in full leaf till the month of june.

GLINUS. (Γλινος *or* Γλινος *is the name of a tree in Theophraſtus.*)

   Stem ſhrubby, leaves obovate plaited, calycine leafleſs ovate.

DESCRIPTIONS, &c.

1. Root annual. Capſule ovate pyramidal, thin, puſtuled by the protuberating ſeeds. Partitions inſerted in the middle of the valves. Seeds fixed by means of very long umbilical cords to the central angle of the cells: there are about fifty in each cell, kidney-ſhaped with a beak, ſtudded with thick, ſcattered dots, ſhining and ſurvginous: integument double; albumen ſcarcely any; embryo ſpiral [a].

Native of the South of Europe and the Levant. Introduced in 1788, by Monſ. Thouin [b].

2. Native of the Eaſt Indies. Stems ſcarcely the ſize of packthread, proſtrate, diffuſed, ſomewhat branched. Branched alternate, both they and the ſtems tomentoſe at top, but with hairs leſs diſtinct than in the firſt ſpecies. Leaves petioled, two or four together, ſomewhat ſharp at the baſe, without veins or nerves, with ſtellate hairs ſhorter than in G. lotoides. Peduncles at the joints, aggregate, ſhort.

3. This has the ſame habit with the two others. The whole plant is hoary with very cloſe hairs, longer than in the firſt ſpecies. Stem very much and dichotomouſly branched; branches diffuſed, jointed, a little thicker at the joints. Leaves two or four at the joints, acute at the baſe, ſubretuſe. Flowers axillary, ſeveral. Peduncles very ſhort. Spinules rigid, minute, from the baſe of the peduncles, permanent. Capſule as in G. lotoides [c].

Native of Arabia.

DESCRIP

DESCRIPTIONS, &c.

1. Stem ſimple herbaceous. Leaves alternate petioled (altogether like thoſe of *Maranta*); the petioles membranaceous and ſheathing; the ſheaths truncate at the tip. Flowers remote, each involved in an ovate bracte, longer than the flower.

This, and the ſecond and third ſpecies are natives of the Eaſt-Indies [a].

2. Rumphius makes two varieties of this, the great and the ſmall. The former has a very ſtraight firm ſtem, from fourteen to eighteen feet in height, two inches in diameter at bottom, naked for ſix feet from the root, and ſtout enough for walking canes; the upper part is ſoft and is eaten in ſome places. Leaves three feet long and more than two hands broad, thin, ſmooth, with many parallel tranſverſe veins, bending upwards near the edge, forming ſlight ridges on the upper and furrows on the lower ſurface. The trunk terminates in a jointed ſtem, three ſpans in length, with a narrow boat ſhaped leaf at each joint, hollowed above, and of a duſky red colour. Fruit the ſize of a pigeon's egg, red.

The leaves of the ſmaller ſort are more wandering, narrower, and draw more to a point at the baſe. The primary ſtem is two or three feet in length, and leafleſs; producing abundance of oblong flowers, in bunches like the Hyacinth.

3. Stem from ſeven or eight to twelve or fourteen feet high, the thickneſs of a finger. Leaves from fourteen to ſixteen inches long, and from four to ſix fingers broad, ſmooth and dark green above, pale green and lanuginoſe beneath. The fructification iſſues from the ſide of the ſtem, eighteen inches or two feet above the root, in a ſpathed bunch or ſpike a hand in length, containing many white flowers, which are ſucceeded by fruit reſembling grapes, but larger, white, becoming black or of the colour of ſmoke, and ſometimes eaten [b].

4. The ſtem is ſheathed with leaves, ſimple, round, ſtreaked, ſmooth, upright, two feet high or more. Leaves few, acuminate, ſmooth, very finely ſtreaked obliquely, a little longer than the ſheathing petioles, very thin except the midrib which is thick, deep green above, paler beneath, a ſpoot long and two inches broad. Flowers many. Rachis flexuoſe, a hand in length. Peduncles ſcarcely a line long, nodding a little, one-flowered. Style filiform. Capſule ovate, augmented by the permanent baſe of the corolla and ſtyle, ſmooth, red, the ſize of the hep of the wild roſe. Seeds ſurrounded by a white connecting membrane, angular, ſmooth, brown.

Native of Japan; where the fruit is ripe in december and january [c].

DESCRIPTIONS, *&c.*

[Root perennial. Stem ſhrubby or herbaceous, ſimple, uſually with one head of flowers at top. Root-leaves often ſpatulate, emarginate-acuminate; ſtem-leaves ſmall or ſcarcely any. *G. Alypum* differs, in having the common calyx turbinate and very imbricate; corolla ligulate three-toothed, ſtigma bifid; ſtem becoming ſhrubby and branched, with the habit of *Protea*[a]. The leaves of all the Globularias dry black. The corollas are blue.

1. This riſes much higher than the next ſpecies, having a hard white wood with a large pith and a ſcabrous light brown or gray bark; the branches towards their ends very thick ſet with leaves, without any order; they are two inches long, and a third part of an inch broad in the middle; the nerves yelloiſh green. Flowers ſmall, blue, in round heads[b].

Native of Madeira. Introduced in 1775, by Sir Joſeph Banks, Bart. It flowers in july and auguſt[c].]

2. This has a hard woody ſtem, about two feet high, with many woody branches, beſet with leaves like thoſe of the Myrtle. The flowers are produced on the tops of the branches in a ball, and are of a blue colour.

[Native of the South of Europe. As about Montpellier, and in many parts of Narbonne and Provence. About Valentia, and ſeveral other places in Spain. In the county of Nice, and on the ſea coaſt of Uneglia. Alſo in Barbary. It flowers from auguſt to november. Cultivated in 1739, by Mr. Miller[d].

From the violent purging quality of this ſhrub, it acquired the name of *Crutex* or *herba terribilis*; and in Engliſh *Herb Terrible*: but in the abundance of purging medicines that we poſſeſs, this is ſeldom if ever uſed.

3. Stem ſhrubby. Leaves rigid, thoſe next the root rounder and cordate, but the ſtem-leaves pointed[e].

4. Stem ſlender, upright, covered with leaves, from an inch and half to ſix inches in height; and ſometimes more, ſomewhat angular, very ſimple, ſmooth, one-flowered. Root-leaves numerous, like thoſe of the Daiſy, but thicker, petioled, placed in a ring, ovate, obtuſe, quite entire, emarginate, the nerve produced into a ſmall awn or point: ſtem-leaves alternate, nearer to ſeſſile, ſmaller, three-toothed, four lines broad, from an inch to an inch and half in length: all ſmooth and of a bright green. Calyx of each floret hairy, and cloſed with villoſe hairs, the whole appearing rough. Corollets of a fine blue. Anthers, and ſtyle of the ſame colour. Germ villoſe[f].

Scopoli obſerves that the leaves of the former year are emarginate, with a dagger point in the middle: but the freſh leaves three-toothed. He adds, that the ſtamens are ſhorter than the ſegments of the upper lip.

Native of many parts of Europe, as Sweden, the South of France, Germany, Switzerland, Auſtria, Carniola, Hungary, Savoy, Italy, Spain. I gathered it on mont Saleve in flower, in april 1779. It uſually flowers in may and june; and was cultivated by Mr. Miller in 1739. Parkinſon ſays it was (1629) very rare in our Engliſh gardens.

In Gerarde's time (1597) the blue Daiſy, or Globe Daiſy, as he calls it, was a ſtranger in England. Johnſon (Ger. emac.) gives only two figures, and adds that one might have ſerved, for they differ but in the tallneſs of their growth, and in the breadth of their leaves. He ſays nothing of their being cultivated in our gardens.

It varies with a white flower; and with a leafleſs ſtalk.

[a] Juſſieu. [b] Sloane. [c] Hort. kew. [d] Ibid. [e] Blumier. [f] Krocker.

5. Root-leaves ſeveral, ſmall, ſtiff, notched, and at each notch a prickle. Stem a hand in height, dark green, with oblong, narrow leaves at the baſe, not notched but ending in prickles. Head of flowers longer than in the foregoing, hairy as in *Sc. Succiſa.*

Found by Albinus on the mountains of Granada[a]. It flowers in may. Cultivated by Mr. Miller before 1752[b].

6. Root large, woody producing many tufts of leaves. Leaves gradually widening from the baſe, emarginate, with the nerve ending in a ſhort awn or ſpinule. Stem naked, except one little ſtrap, two inches high or little more, terminated by one head of flowers, ſmaller than in the other ſorts[c].

Native of Switzerland, Auſtria, Carniola, Hungary, Piedmont, Aragon. Ray found it at the foot of mont Saleve in Savoy near Geneva. It flowers in june and july. Cultivated in 1759, by Mr. Miller[d].

7. Somewhat larger than the foregoing, both in the leaves and flowers. Leaves firm like thoſe of the Bay. Stem naked, except a few little ſtraps or ſcales, ſix inches high[e]. Stem a little higher than the leaves. Flowers uſually trifid, but ſometimes quadrifid[f].

Native of Switzerland, Auſtria, Carniola, Savoy and Piedmont. Ray obſerved it near the Grand Chartreux in Dauphiné. It flowers in july. Cultivated in 1739, by Mr. Miller[g].

8. Root-leaves very many, obovate, naked, ſharp, ending in the petioles. Stem a foot high, herbaceous, quite ſimple; the leaves on it very ſmall, lanceolate, alternate, remote. There are from ſeven to ten heads at the top of the ſtem. Found by Tournefort in the Levant[h]. Cultivated by Mr. Miller in 1739.]

PROPAGATION AND CULTURE.

2. This plant may be propagated by cuttings, which ſhould be cut off in april, juſt before they begin to make new ſhoots; the cuttings ſhould be planted into pots filled with light freſh earth, and then placed into a very moderate hot-bed, obſerving to water and ſhade them until they have taken root, when they may be taken out of the bed, and inured to bear the open air by degrees. In ſummer theſe plants may be expoſed with other hardy exotic plants, and in winter they ſhould be placed under a hot-bed frame, where they may enjoy the free air in mild weather, but ſhould be ſcreened from hard froſt, which will deſtroy them, if they are expoſed thereto, but in mild winters they will live in the open air. This plant never produces good ſeeds in this country.

4, 5, 6, 7. may be propagated by parting the roots after the manner of Daiſies. The beſt ſeaſon for parting and tranſplanting of the plants is in ſeptember, that they may take new root before the froſty weather comes on. They ſhould be planted in a ſhady ſituation, and require a moiſt loamy ſoil, in which they will thrive much better than in a light ground and an open ſituation; but the plants ſhould not be removed oftener than every other year, if they are required to flower ſtrong.

1, 8. Theſe are ſomewhat tender, and ſhould be ſheltered from the froſt in winter, under a frame, but in ſummer ſhould be expoſed with other hardy exotic plants, and will require to be frequently watered in dry weather. This may be propagated by ſeeds, or by parting their roots, as was directed for the fourth ſort.

2. Gloriosa simplex.
Lin. syst. 325. *Reich.* 2. 49. *mant.* 62.
G. cærulea. *Mill. dict. n.* 2.
Leaves acuminate.

DESCRIPTION, *&c.*

1. This has a long fleshy root of a whitish colour, and a nauseous bitter taste, from the middle of which arises a round weak stem, requiring support, and with that growing to the height of eight or ten feet. Leaves smooth, about eight inches long, and one inch and a half broad at the base, growing narrower till within two inches of the end, which runs out in a narrow point, and ends in a tendril. Flowers at the upper part of the stem, from the side, on slender peduncles, hanging down, at first of an herbaceous colour, but changing to a beautiful flame-colour.

[Stem a fathom in height, round, with two opposite, lateral branches; above these it puts forth a peduncle from each axil. Leaves alternate, but under the branches in threes[a].

Capsule turbinate, the outer coat leathery and opaque: valves rounded at the back, marked with a depressed longitudinal line, smooth; within streaked with transverse parallel lines, shining like silk, bay-yellow, gaping by the inner suture. The partitions are formed from the edges of the valves bent in; they are folded, and united at the axis of the fruit. Seeds as far as twelve in each cell, acuminate towards the navel, scarlet. Parts of the embryo folded together[b].

This fine plant is native of Guinea, as well as the East Indies; and was introduced here in 1690, by Mr. Bentick[c].]

It flowers in june and july, but seldom perfects seeds in this country. The stalks decay in autumn, the roots remain inactive all the winter, and new stalks come out in march. The roots and every part of the plant are poisonous.

2. Stem climbing. Leaves smooth, about three inches long and two broad, ending in acute points, but having no tendril. The stalks as yet have not grown more than two feet high, but have the appearance of climbing. The leaves have a strong disagreeable scent on being handled. It is said to have a blue flower. The seeds were sent to Mr. Miller by Monsr. Richard, gardener to the French King at Trianon, and were brought from Senegal by Monsr. Adanson.

[This plant has not appeared in any of the gardens either in France or England, nor was there any specimen of it in Mr. Miller's herbarium; it is doubtful therefore what it might have been.]

[a] Linn. mant. [b] Gærtner. [c] Hort. kew.

PROPAGATION AND CULTURE.

As these plants rarely produce seeds in this country, they are generally propagated by their roots; those of the first sort creep and multiply pretty fast, but the second has not as yet put out any offsets; but as the plants are young, we cannot as yet say how they may increase when they are of a proper age. These roots may be taken out of the ground when their stalks are decayed, and preserved in sand during the winter season, but they must be kept in the stove, or a warm room, where they can receive no injury from the cold; and in the spring they must be planted in pots filled with light earth, and plunged into the tan-bed in the stove; but others chuse to let the roots continue in the ground all the winter, keeping the pots always in the tan-bed; where this is practised, the roots should have very little water in the winter; for as they are then in an inactive state, moisture at that time frequently rots the roots.

Towards the latter end of march, or the beginning of april, their stalks will appear, when there should be some tall sticks put down by them to support them, otherwise they will trail over the neighbouring plants, and the first sort will fasten to the plants by the tendrils. The stalks of this sort will rise ten or twelve feet high, if the roots are strong, and some of them will produce two or three flowers; these make a fine appearance in the stove, during their continuance, which is seldom more than ten days or a fortnight. In summer, when the plants are growing, they will require frequently to be watered, but they must not have it in too large quantities, for they are very subject to rot with much wet at any season. Those roots which are not taken out of the pots in winter, should be transplanted and parted the beginning of march, before they put out new fibres, or stalks, for they must not be removed when they are in a growing state; the pots should not be too large; for unless they are confined, they will not put out strong stalks; the largest roots may be planted in twopenny pots, but the small ones will require only pots of about five or six inches over at the top.

SPECIES.

Glossoma guianensis.
Votomita guianensis. *Aubl. guian.* 91. *t.* 35.

DESCRIPTION, *&c.*

This is a middle-sized shrub, five or six feet high, the bark brown, the wood yellow, hard and compact; branches jointed, four-cornered. Leaves opposite, cruciate, six inches and a half long, and two and a half wide, entire, smooth, thick, elliptic, acuminate, on very short petioles. Stipules short, acute, at the base of the petioles, deciduous. Peduncles axillary, bearing two, three, or four flowers, each on its proper pedicel, bracted at the base. Corolla white.

Native of Guiana, and flowering in september[4]. Votomita is the vernacular name.

GLOSSOPETALUM. (*Tongue-petalled: each petal having a ſtrap or tongue at the end.*)

Leaves ſmooth.

2. Gloſſopetalum hirſutum.
Goupia hirſuta. *Aubl. guian.* 296.
Leaves hairy.

DESCRIPTION, *&c.*

1. This is a tree, the trunk of which riſes to the height of ſixty feet and more, and is from two to three feet in diameter. The bark is ſmooth and gray; the wood white and of a looſe texture. Leaves alternate, ſmooth, ſhining, firm, entire, ovate-lanceolate, ending in a long point. The midrib divides them unequally. The petiole is ſhort, and has two ſmall, narrow, deciduous ſtipules at the baſe. Peduncles ſolitary, axillary, two inches long, bearing many flowers in a ſpherical head. Corolla yellow. Berry black.

Native of Guiana, flowering in november. The natives make canoes of the trunk[4].

2. The trunk of this ſpecies is only from twenty to twenty-five feet in height. The bark is wrinkled, blackiſh marked with white. The leaves are covered with ſhort hairs on both ſides. Theſe are uſed againſt inflammations in the eyes; they are bitter, as is alſo the bark.

Native of Guiana and Cayenne[4].

Goupi is the vernacular name.

GLOXINIA. (*So named by L'Heritier, in memory of Benjam. Petr. Gloxin of Colmar, author of* Obſervationes Botanicæ, *Argent.* 1785. 4to.)

ESSENTIAL CHARACTER.

Cal. ſuperior, five-leaved. *Cor.* bell-ſhaped, with the border oblique. *Filaments* with the rudiment of a fifth, inſerted into the receptacle.

SPECIES.

1. Gloxinia maculata. *Spotted Gloxinia.*
L'Herit. ſt. nov. 149. *Ait. hort. kew.* 2. 331.]

Martynia perennis. *Lin. ſpec.* 862. *Reich.* 3. 142. *hort. cliff.* 322. *t.* 18. *Mill. dict. n.* 2. *Ehret. pict. t.* 9. *f.* 2. *Medic. bot. beob.* 1783. *p.* 238. *Glox. obſ. bot.* 13.

DESCRIPTION, *&c.*

Root perennial, thick, fleſhy, divided into knots which are ſcaly, ſomewhat like thoſe of Tooth Stems ſeveral, about a foot high, thick, ſucculent purpliſh. Leaves oblong, thick, ſeſſile, ſerrated, rough on their upper ſide, where they are of a dark green, but their under ſide is purpliſh. Stem terminated by a ſhort ſpike of blue flowers: [or rather an erect raceme, leafy or bracted; in which the flowers are axillary, ſolitary, pedunculed, bright blue, and ſweet-ſcented. Calyx coloured at the tips of the leaflets underneath. Corolla hirſute on the outſide, inſerted into the receptacle, larger than the calyx: the baſe is gibbous in front, very large, melliferous within and dark purple[4].

Native of South America,] where it was diſcovered about Carthagena by Mr. Robert Millar, who ſent the ſeeds to Europe. [Mr. Philip Miller cultivated it in 1739[5].]

PROPAGATION AND CULTURE.

This plant muſt be conſtantly preſerved in the ſtove, and plunged into the bark-bed. During the winter ſeaſon much water will rot the roots. In the middle of march, juſt before it begins to ſhoot, the roots may be parted, and tranſplanted into middle-ſized pots, filled with rich light earth, and plunged into the bark-bed, which ſhould then be renewed with freſh tan. When the plants come up, they muſt be frequently refreſhed with water in ſmall quantities, and as the ſeaſon becomes warmer a large ſhare of freſh air ſhould be admitted. They ſhould not be placed where they are over-hung or ſhaded by other plants; nor ſhould they be ſhifted or tranſplanted when they are in leaf, for that will prevent their flowering. Since this plant increaſes very faſt by the roots, there is no neceſſity for uſing other methods to propagate it; otherwiſe the ſhoots of the young ſtalks will take root, if they are planted in pots filled with light earth, and plunged into a hot-bed, during any of the ſummer months.

Claſſ. 17. 4. Diadelphia Decandria.
Nat. order of *Papilionaceæ*, or *Leguminoſæ*.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, compreſſed; *mouth* two-lipped: *upper lip* emarginate, obtuſe; *lower* longer, trifid, acute; the middle tooth more produced.

COR. papilionaceous. *Banner* obcordate, the ſides bent down, the back gibbous, the tip emarginate, ſtraight, repelled from the keel. *Wings* oblong, towards the tip ovate, ſmall, bent downwards. *Keel* linear, ſickle-ſhaped, bent upwards, at the tip preſſing the banner upwards, obtuſe, towards the tip broader.

STAM. *Filaments* diadelphous (ſimple and nine-cleft) only a little divided at the tip, rolled back. *Anthers* ſimple.

PIST. *Germ* oblong. *Style* cylindric, rolled back in a ſpiral. *Stigma* obtuſe.

PER. *Legume* oblong.

SEEDS kidney-form.

OBS. G. Apios & fruteſcens *have two-celled legumes*. G. monoica *is ſingular in this family.* —*This is a difficult genus, and being made up of heterogeneous ſpecies, it requires farther conſideration.* G.

ESSENTIAL CHARACTER.

Cal. two-lipped. *Cor.* the keel turning back the banner at the tip.

SPECIES.

[1. Glycine ſubterranea.
Lin. ſpec. 1023. *ſyſt.* 659. *Reich.* 3. 452. *dec.* 37. *t.* 19. *Lour. cochinch.* 457.

Leaves ternate three-lobed villoſe; racemes axillary.
7. Glycine javanica. *Java Glycine.*
Lin. ſpec. 1024. *Reich.* 453. *Thunb. in Linn. tranſ.* 2. 340.
Leaves ternate; ſtalk villoſe; petioles rough-haired; braſſes lanceolate minute.]
8. Glycine comoſa.
Lin. ſpec. 1024. *ſyſt.* 659. *Reich.* 453. *Gron. virg.* 85-137.
Phaſeolus marianus ſcandens, flor. comoſis. *Petiv. muſ.* 453.
Leaves ternate hirſute; racemes lateral.
[9. Glycine phaſeoloides.
Swartz prodr. 105. *Brown. jam.* 296. 2. *Plum. cat.* 12. (Phaſeolus.)
Leaves ternate villoſe underneath, racemes terminating.]
10. Glycine tomentoſa. *Downy Glycine.*
Lin. ſpec. 1024. *ſyſt.* 659. *Reich.* 454. *Gron. virg.* 81-106. *Dill. elth.* 30. *t.* 26. *f.* 29. (Anonis).
β. Dolichos pubeſcens. *Lin. ſpec.* 1021. *Jacqu. hort.* 2. *t.* 101.
Leaves ternate tomentoſe; racemes very ſhort, axillary legumes two-ſeeded.
[11. Glycine reticulata. *Nettled-leaved Glycine.*
Swartz prodr. 105. *Ait. hort. kew.* 3. 35. *Vahl. ſymb.* 3. 88.
Leaves ternate oblong-lanceolate pubeſcent, the veins like net-work underneath; racemes axillary ſubſeſſile; legumes oblong compreſſed.
12. Glycine bituminoſa. *Clammy Glycine.*
Lin. ſpec. 1024. *Reich.* 454. *Gærtn. fruct.* 2. 343. *Herm. lugdb.* 492. *t.* 493. (Phaſeolus).
Leaves ternate; flowers racemed; legumes tumid villoſe.
13. Glycine Nummularia.
Lin. ſyſt. 660. *Reich.* 454. *mant.* 571.
Leaves ternate very obtuſe; racemes with flowers in pairs; legumes ſeſſile ſubcylindrical compreſſed.
14. Glycine labialis. *Labiate Glycine.*
Lin. ſyſt. 660. *ſuppl.* 325.
Twining; leaves ternate, obovate, ſomewhat hoary; flowers axillary heaped, corolla ſomewhat two-lipped.
15. Glycine ſtriata.
Lin. ſyſt. 660. *ſuppl.* 326. *Jacq. hort.* 1. 32. *t.* 76.
Twining; leaves ternate oblong very ſoftly hoary; racemes axillary the length of the leaves; legumes extremely hirſute.
16. Glycine roſea.
Forſt. fl. auſtr. n. 271.
Twining; leaves ternate, leaflets cordate-ovate acute quite entire, peduncles three-flowered; legumes compreſſed keeled one-ſeeded.
17. Glycine lucida. *Shining Glycine.*
Forſt. fl. auſtr. n. 272.
Twining; leaves ternate, leaflets ovate acuminate quite entire; racemes terminating glandular, pedicels in threes; legumes inflated containing two ſeeds.
18. Glycine ſuaveolens. *Sweet-ſmelling Glycine.*
Lin. ſyſt. 660. *ſuppl.* 326.
Shrubby, upright, hoary; leaves ternate, ovate, acute, flowers axillary, ſolitary; legumes containing two ſeeds.]
19. Glycine Apios. *Tuberous-rooted Glycine.*
Lin. ſpec. 1025. *ſyſt.* 660. *Reich.* 455. *hort. upſ.* 227. *cliff.* 365. *Gron. virg.* 107. *Mor. hiſt.* 2. 105. *ſ.* 2. *t.* 9. *f.* 1. (Aſtragalus.)

Leaves unequally pinnate, ovate-lanceolate, with ſeven leaflets.

20. Glycine fruteſcens. *Shrubby Glycine*, or *Carolina kidney-bean-tree.*
Lin. ſpec. 1025. *ſyſt.* 660. *Reich.* 455. *hort. cliff.* 361. *Hort. angl. t.* 55.
Leaves unequally pinnate; ſtalk perennial.

21. Glycine monophylla. *Simple-leaved Glycine.*
Lin. ſyſt. 660. *Reich.* 455. *mant.* 101. *Pluk. amalth. t.* 454. *f.* 8. (Lens.)
Crotalaria Afarina. *Berg. cap.* 194.
Leaves ſimple, cordate; ſtalk pubeſcent, three-cornered.

[22. Glycine picta.
Vahl ſymb. 2. 81. *Aubl. guian.* 766. *t.* 306. (Cytiſus).
Leaves ternate, lanceolate, villoſe. racemes axillary, pedunculed, ſtem ereſt, ſhrubby.

23. Glycine bimaculata.
Curt. magaz. 263.
Stem twining, ſmooth and even, leaves ſimple, cordate-oblong, racemes many-flowered.

24. Glycine rubicunda.
Curt. magaz. 268.
Stem perennial, twining, leaves ternate; leaflets ſub-oval, quite entire, peduncles ſubtriflorous.

25. Glycine coccinea.
Curt. magaz. 270.
Leaves ternate, leaflets roundiſh, waved.

DESCRIPTIONS, &c.

The Glycines are moſtly perennial * herbaceous plants, with twining ſtems, ſometimes ſhrubby at the baſe; in the two firſt ſpecies creeping, and ripening their fruit under ground. In the nineteenth and twentieth ſpecies the leaves are unequally pinnate; in the laſt they are ſimple; in all the reſt ternate: the leaflets of all as in *Dolichos articulata*, with their petioles in like manner awned, or glandular: the ſtipules diſtinct from the petiole: the peduncles axillary, with one or two flowers, or elſe with many flowers in racemes, frequently having a pair of bractes. If the legume be bilocular in the two ſpecies which have bipinnate leaves, they are perhaps of a diſtinct genus, or might with more propriety be aſſociated with the *Aſtragali*. It may be doubted whether the flowers of *G. monoica* be really ſexually diſtinct, or rather hermaphrodite, as in other leguminous plants that ripen their fruit under ground. It is alſo a doubt whether *G. momophylla*, the only ſpecies with ſimple leaves, belongs to this genus [a].

Two of the ſpecies come from the Cape of Good Hope; five from the iſlands in the South Seas. The reſt are natives of the Eaſt and Weſt-Indies, Virginia and Carolina. Europe produces none of them.

1. *Root* annual. *Stalks* ſeveral, a ſpan in length, very rigid, cloſe to the ground, or deſcending to it, round, hairy, unbranched. *Leaves* alternate, upright, petioled; leaflets ſpreading, petioled, oblong, quite entire, emarginate, ſmooth, veined, flat, nearly equal: petioles linear, three-ſided, ſtreaked, very long, ſwelling at their inſertion, very ſmooth, upright; petiolules very ſhort, round, hirſute, bowed in. *Stipules* two, lateral, permanent, very ſhortly peltate, ovate, quite entire, very ſmall, hairy, flat; partial ſtipules to each lateral leaflet, ſolitary; to the middle one two, oblong, ſmooth, ſeſſile, upright, concave. *Peduncles* axillary, ſolitary, drooping, filiform, hairy, as long as the internodes of the ſtalk, ending in a globular ſmooth callority, below which are the pedicels, oppoſite, half the ſize of the peduncle, round, ſmooth, reflex, rigid. *Flowers* upright, the ſize of thoſe in *Ervum tetraſpermum*. Calyx four-cleft; the ſegments lanceolate, ſharp, ſtraight, the uppermoſt larger than the reſt, and emarginate: it is ſmooth, green, and ſhorter than the tube of the corolla. Corolla pale yellow: banner obovate, ſtreaked, upright: wings very blunt, as long as the banner, ſpread out: keel as long as the wings, blunt. Germ linear, ſmooth, green: ſtyle hirſute on the upper ſide. Legume lens-ſhaped, ſmooth; containing one round ſeed.—As ſoon as it is out of flower the peduncle perforates the earth as in *Trifolium ſubterraneum*, and *Arachis hypogæa*, and the ſeeds ripen under ground. It is a native of Braſil and Surinam, whence it was brought in the year 1762, by Dahlberg, and flowered in the bark ſtove, in the botanic garden at Upſala, but did not ripen its ſeed there [b].

It is common on the eaſtern coaſt of Africa, the ſeeds which were brought thence by Loureiro, grew, bore flowers and fruit for two years in Portugal, but the third year did not produce any ſeed [b].

In Surinam it is called *Gobbe Gobbe*, and is planted there in a ſandy ſoil with the addition of a little clay. It bears abundance of fruit, which is a welcome repaſt to the inhabitants, boiled whilſt yet unripe like peas [c].

2. Stalk gray, with reverſed hairs. Stipules ovate, upright. Racemes many-flowered. Flowers like thoſe of *Vicia Cracca*, with the banner pale violet, the wings and keel white; they have ſtamens and piſtils, but the former being effete, they bear no fruit; the lower peduncles are longer, hanging down, and one-flowered; this flower has the rudiment of a calyx and piſtil, but no corolla; it bears a legume containing one or two ſeeds. Here, therefore, the laws of fructification are the ſame as in *Viola mirabilis* [d].—This alſo perfects the fruit underground, like *Lathyrus ſubterraneus* [e].—Native of North-America, and Japan. It flowers here in ſeptember. Introduced in 1781, by Mr. William Curtis [f].

3. Root biennial.—Native of the Eaſt-Indies; where it was found by John Gerard Koenig, M. D.—Introduced in 1778, by Sir Joſeph Banks, Bart. It flowers in june and july [g].

4. Stems aſh-coloured, the thickneſs of a quill, ſmooth: the younger branches green and herbaceous. Leaves petioled; leaflets acute. Stipules to the common petioles awl-ſhaped, ſhort, ſetruginous. Younger branches and leaves ſomewhat rugged to the touch from hairs not viſible to the naked eye. Racemes axillary, lateral, ſlender, elongated, many-flowered. Corolla yellow, the banner variegated underneath with purple lines. Legume an inch long [h].

Native of the Weſt-Indies. It was cultivated before 1742, by Robert James Lord Petre: and flowers in ſeptember and octobor [i].

5. The whole plant is proſtrate, and does not climb. The root is annual. The flowers are yellow, ſmall, and generally two together. Legumes cylindric.—Native of the Eaſt-Indies [k]. It is probably a Phaſeolus.

6. Stem filiform, angular, twining, flexuoſe, tomentoſe, as is alſo the whole plant. Leaves petioled: all the leaflets, eſpecially the middle one, three-lobed, ſharp, nerved, half an inch in length; the middle one larger, and on a longer petiole. Raceme peduncled, with two, four or five flowers; in which it differs from *G. tomentoſa*. Native of Japan [l].

7. Stem twining, as in *Phaſeolus*, with yellow, reflex hairs ſcattered over it. Leaves of *Phaſeolus*. Pedicels yellow, with cloſe hairs. Stipules, to the petioles oval-oblong, to the peduncles lanceolate. Peduncles the length of the leaves, terminated by an ovate-oblong, cloſe ſpike of nodding violet-coloured flowers, with very minute bractes between them.—Native of the Eaſt-Indies [m]; and near Naga-

* The firſt is annual, and the third biennial. The fifth is ſaid to be annual, and perhaps another or two may be ſo.

[a] Juſſieu. [b] Loureiro. [c] Linn. dec. [d] Linn. ſpec. [e] Linn. ſyſt. [f] Hort. kew. [g] Ibid. [h] Jacquin. [i] Hort. kew. [k] Linn. mant. [l] Thunberg. [m] Linn. ſpec.

ſaki in Japan, where it is called *Fojo Mame*, and flowers in ſeptember and october [a].]

8. This riſes from two to three feet high, with ſlender herbaceous ſtalks. Leaves ſeſſile; leaflets oval-lanceolate, ending in acute points. Flowers axillary, lateral; the naked part of the peduncle is about two inches long; the ſpike is about the ſame length, and recurved. Corollas ſmall, of a fine blue colour. [Seeds with purple ſpots [b]. Native of Virginia, in moiſt ſhady places. It flowers here in june, and is ſometimes ſucceeded by ſeeds, which ripen in auguſt.

9. Stem twining to a conſiderable height, and bearing many flowers towards the top. The legumes have two ſeeds, and are contracted in the middle [c]. Native of Jamaica and Domingo.

10. Root perennial. Stalks twining, from a foot and half to four feet in height, three-cornered, hairy. A ſingle leaf comes out at each joint, on a foot-ſtalk: leaflets roundiſh, wrinkled, ſet with ſlender hairs, the upper ſurface paler; the middle leaflet ſomewhat wider than the lateral ones. From the boſom of the leaves three or four ſmall flowers come out, on very ſhort peduncles, of a pale yellow colour; the banner broadiſh, the wings narrow, and the keel compreſſed (ſhorter, and not wreathed or ſpiral, as in *Phaſeolus*). Calyx four-cleft almoſt to the baſe; the upper ſegment broader than the reſt, and bifid: this part is ſmooth, all the reſt of the plant is hirſute. Legumes the form and ſize of the Lentil, brown when ripe, ſomewhat hirſute, containing two ſeeds, ſmaller than Lentils, and more ſwelling, browniſh, and marked with paler ſpots. Native of Virginia, where it is called *Mountain Pea*. It flowers from june to ſeptember, and ripens the early flowers in autumn.

β. *Dolichos pubeſcens* of Linneus's ſpecies is probably only a variety of this ſpecies, the banner not being bent back. The ſtature of this variety is that of *Phaſeolus vulgaris*, but the whole plant is ſofter and pubeſcent. The leaflets are almoſt naked on the upper ſurface; the middle one inclining to rhomb-ſhaped, the ſide ones gibbous without, and lanceolate within. Flowers three together, ſeſſile, yellowiſh white, with a brown ſpot on the banner. Legumes oblong, pubeſcent, a little bowed back [d].

11. Stem twining, angular, ſoftly villoſe, ſubcanеſcent. Leaves petioled: leaflets alſo petioled, the middle one an inch and half long, the ſide ones a little ſmaller, all three acute, villoſe on both ſides, ſoft, ſomewhat wrinkled, netted, and paler underneath. Petioles tomentoſe. Stipules ovate. Racemes axillary, ſolitary, longer than the leaves. Pedicels ſolitary, diſtant. Bractes ovate, attenuated, deciduous. Calyxes five cleft, the clefts linear-lanceolate, attenuated. Legume ſharp at both ends, pubeſcent eſpecially on the edges, brown. Seeds two [e].

Native of Jamaica. Found there by Swartz.—Introduced here in 1779, by John Fothergill, M.D. [f].

12. Stem twining, obtuſe-angled, pubeſcent. Leaflets ovate, ſmooth, only ſomewhat pubeſcent underneath. Stipules ovate, acuminate, nerved. Racemes axillary, longer than the leaf, pubeſcent. Corollas yellow, ſtreaked, on the outſide and at the tip of the keel violet-coloured, extremely obtuſe as in *Hedyſarum*. Stamens really diadelphous, not as in *Ononis*. Legumes rough with hairs [g], blown up, like thoſe of *Crotalaria*. Seeds four, ſmall, globular, a little flatted, black [h].—Native of the Cape of Good Hope. Introduced in 1774, by Mr. Francis Maſſon. It flowers from april to ſeptember [i].

13. Stem herbaceous, twining, angular, pubeſcent. Leaves alternate, remote, ſubpubeſcent: leaflets wedge-orbiculate, equal, broader than long, the lateral ones ſeſſile. Petioles the length of the leaves. Stipules ovate, deciduous. Peduncles axillary, ſolitary, filiform, longer than the leaves, ſtanding out, undivided. Flowers in three pairs, very remote, ſeſſile, reflex, ſmall. Legumes the ſize of the white Lupin ſeed, very much flatted, mucronate by means of the permanent ſtyle; containing only one ſeed. Native of the Eaſt-Indies [k].

14. Stalk twining, the thickneſs of a thread. Leaves petioled: leaflets obtuſe, equal, ſcarcely tomentoſe underneath. Stipules none. Peduncles very ſhort. Calyx tubular, five-toothed, the teeth nearly equal. Corolla white, the ſame ſize as in the Lentil: banner almoſt upright, whitiſh; wings bent down to the lip, the inner ſide turned outwards and fleſh-coloured; keel roundiſh, ſhort, conſiſting of two petals, cohering only at the tip, hence it is a labiate flower. Anthers yellow, few of them perfect. Style ſhort. Legume linear, compreſſed, as it were jointed; with a dagger-point which is upright with reſpect to the upper ſuture, and rigid. Seeds ſeven to nine, roundiſh, compreſſed, yellow. Native of the Eaſt-Indies [l].

15. Stems woody, round, hirſute. Leaflets ovate, obtuſe, with a little terminating briſtle, quite entire, covered with very ſhort cloſe hairs, and hence ſoft, ciliate, and ſomewhat hoary on the back; the inner diviſion of the ſide-leaflets is a little narrower than the outer. Petioles hirſute, round, not grooved or angular. All the ſtipules linear and acuminate. A ſolitary and hirſute raceme proceeds from the axils of the leaves, and is frequently accompanied by a new branchlet. It has from ſix to thirty flowers, by pairs or in threes at ſhort intervals, on their proper pedicels. Calyx hairy, one third ſhorter than the petals, the tube bell-ſhaped and very ſhort, the limb four-cleft, the clefts lanceolate and acuminate, the loweſt a little longer, the uppermoſt broader, not emarginate. Banner of the corolla ſtriated, purple, green at the baſe, without any calluſes: wings erect, narrower and ſhorter than the keel, purple: keel almoſt without colour, the length of the banner, cloven at the back almoſt to the top, emarginate in front at the tip. Germ hairy, linear, compreſſed: ſtyle of the ſame length, and in the ſame ſituation with the ſtamens, ending at top in a blunt, duſky, ſimple ſtigma, not bearded. Legume compreſſed, acuminate, brown, very hairy, one or two inches long, ſtraight, or a little incurved. Seeds ſeveral, ſhining, brown variegated. Native of South America. It flowered in the Vienna garden in 1770 [m].

16, 17. Natives of the Society iſles [n].

18. A ſhrub, the whole of which is hoary, clammy and ſweet. Leaves petioled. Stipules ſubulate. Peduncles upright, filiform, jointed and bracted in the middle, one-flowered. Bractes in pairs, ſubulate, caducous. Flowers drooping. Calyx bell-ſhaped, divided into four ſubulate ſegments; the uppermoſt of which is cloven. Banner of the corolla orbiculate, upright, yellow, above the claw with blood-red ſtreaks: keel as in *Indigofera*. Stigma flat. Legume compreſſed, linear, ſhort, almoſt rhomb-ſhaped, hoary, with a tranſverſe groove. Seeds black, ſmooth, with a callous, whitiſh heart.—Found by Koenig among rocks near Madras, in the Eaſt-Indies [o].]

19. This has tuberous roots, from which come out in the ſpring ſlender twining ſtalks, which riſe to the height of eight or ten feet. Leaves compoſed of three pairs of leaflets, terminated by an odd one. The flowers come out in ſhort ſpikes from the ſide of the ſtalks. They have little ſcent, appear in auguſt, but do not produce ſeeds in England.

[The genus of this is doubtful, perhaps it may be nearer to the *Aſtragali*, but the corolla is different, eſpecially in the linear keel much ſickle ſhaped: colour dark purple [p], duſky fleſh-colour, or rather ſuliginous [q], or a ſullen bluſh-colour [r].

Cultivated here in 1640[z]. Parkinſon calls it *Virginia Earth-nuts*.]

20. This has woody ſtalks, which twiſt themſelves together, and alſo twine round any trees that grow near, and will riſe to the height of fifteen feet or more. The leaves are in ſhape ſomewhat like thoſe of the Aſh-tree, but have a greater number of leaflets. The flowers are produced in cluſters from the axils, and are of a purple colour. They are ſucceeded by long cylindrical legumes, ſhaped like thoſe of the ſcarlet Kidney-bean, containing ſeveral ſeeds, which are never perfected in England.

[Legume, in this and the foregoing ſpecies, two-celled[b]. It flowers from june to ſeptember. Introduced in 1724, by Mr. Mark Catesby[c].

21. Stalks two feet high, branched, the thickneſs of a thread, proſtrate and decumbent, hairy. Stipules in pairs. Leaves quite entire, ſimple, ſomewhat pubeſcent on both ſides, three times as long as the petioles, with a weak point at the tip. Peduncles axillary, ſolitary, one-flowered, capillary, longer than the petioles. Involucre tender, ſubtriſid. Corolla violet-coloured. Germ villoſe. Keel of the corolla obtuſe, as in *Hedyſarum*[b]. Linnæus obſerves that his plant differs in having an upright ſtalk, and narrower leaves. Native of the Cape of Good Hope. —It flowers in auguſt. Introduced in 1787, by Mr. Francis Maſſon[d].

22. This is an upright, branched ſhrub. Branches angular, ſtriated, ſubtomentoſe with purpliſh hairs. Leaves remote, petioled: leaflets alſo petioled, from two to three inches long, lanceolate, attenuated, mucronate, villoſe on both ſides, ſoft, the upper ſurface marked with lines, the lower whiter, netted-veined, the veins purpliſh-tomentoſe. Petiole very ſhort. Stipule oppoſite to the leaf, ſub-biſid; the ſegments awl-ſhaped. Peduncles axillary, ſolitary, half the length of the leaves, tomentoſe; having at the baſe a pair of alternate, approximating, ovate bractes. Pedicels ſhort. Flowers ſpreading, approximating. Calyx hoary, two-lipped[a].

Found in Guiana by Aublet, and in the iſland of Trinidad by von Rohr.

Vahl doubts whether it be really diſtinct from *G. reticulata* of Swartz (n. 11); from which however it is certainly very different. Perhaps it does not belong to this genus.

23. This riſes up with a twining ſhrubby ſtalk to the height of ſix or eight feet and more; multiplying greatly by age it becomes loaded with a profuſion of purple flowers growing in racemes; the richneſs of the corolla is enlivened by two green ſpots at the baſe of the banner. For the moſt part the flowers go off here without producing any ſeed-veſſels; perfect ſeeds, however, have been produced, and a plant has flowered from them in the garden of John Ord, Eſq. at Walcham-Green. It begins to flower in february, and continues during the ſummer. In the nurſeries about town it is known by the name of *G. virens*, the name originally given to this plant by Dr. Solander. The characters do not appear to be peculiarly expreſſive of this genus.

This is one of the firſt plants from Botany-bay that flowered in this country, and it is one of the moſt ornamental[e].

24. Stem ſhrubby, ſlender, twining, five or ſix feet high, and more, red, branched, leafy. Leaves ternate, on petioles from an inch to two inches in length, channelled above, round underneath: leaflets ovate or elliptic, quite entire, the two ſide ones on very ſhort petioles, the end one on a petiole half an inch in length, bending and ſwelling immediately under the leaflet, and having there a pair of deciduous ſtipules. Almoſt the whole plant is covered with hairs preſſed cloſe. Pedunceles uſually in pairs from the axils, tinged with red, as is alſo the calyx, the upper lip of which is emarginate or ſlightly biſid, the lower cut into three awl-ſhaped equal ſegments. Corolla ſcarlet, mixed with dull purple: banner bent back ſo as to lie on the calyx and cover it, ſcarlet at the end and on the ſides, purple in the middle, except towards the baſe, where it is whitiſh; wings the length of the keel, but narrower; ſcarlet towards the tip, but dull duſky red towards the baſe; keel long and narrow, boat-ſhaped, red, readily ſplitting from the baſe upwards. Stamens very manifeſtly diadelphous. Legume very hairy, with the ſtyle remaining a long time.

It flowers from april to june.

Native of New South Wales, whence it was introduced about the ſame time with the foregoing.

25. Shrubby, climbing, growing to the height of many feet, if ſupported, and producing a great number of flowers on its pendant branches. Leaflets nearly round, and in the older ones eſpecially curled at the edges. Flowers for the moſt part in pairs, of a glowing ſcarlet colour, at the baſe of the keel ſomewhat inclined to purple; the bottom of the banner is decorated with a large yellow ſpot, verging to green. It flowers from april to june. Introduced lately from New South Wales[e].

PROPAGATION AND CULTURE.

[Few of theſe plants have yet been cultivated in this country.]

The eighth and tenth are hardy enough to live in the open air in England. They may be propagated by ſeeds, or parting of the roots; the former is the beſt method, where good ſeeds can be obtained: theſe may be ſown on a bed of light earth in the ſpring, and if the ſeaſon ſhould prove dry, they muſt be frequently refreſhed with water, otherwiſe they will remain a long time in the ground before they vegetate: when the plants come up, they muſt be kept clean from weeds in the ſummer, and in the autumn when their ſtalks are decayed, if ſome rotten tanner's bark is ſpread over the ſurface of the ground, it will protect the roots from being injured by the froſt. In the ſpring, the roots ſhould be tranſplanted to the places where they are deſigned to remain, which muſt be in a warm ſheltered ſituation, but not too much expoſed to the ſun, and in a light ſoil, where they will thrive and produce flowers annually. If theſe are propagated by parting of the roots, it ſhould be done in the ſpring, before the roots begin to ſhoot: but they ſhould not be parted oftener than every third year, for if they be frequently removed, they will not flower ſo ſtrong.

[The tenth being the moſt tender of the two, the ſeeds may for greater ſecurity be ſown in a hot-bed; and ſome of the plants kept in the green-houſe, or againſt a ſouth wall, to be protected occaſionally in ſevere weather with dung put to their roots.]

19. This is propagated by parting the roots, and each of the tubers will grow; the beſt time for this is the end of march or beginning of april, before they put out ſhoots. The roots ſhould be planted in a warm ſituation, and in hard froſt covered with tan or mulch to protect them, otherwiſe they will not live abroad in this country: where they have been planted againſt a ſouth wall, they have thriven and flowered extremely well, which they ſeldom do in any other ſituation; and thoſe roots which are planted in pots rarely flower, nor do their ſtalks riſe near ſo high as thoſe which are planted in the full ground.

20. Is increaſed by laying down the young branches in october, which will be rooted well by that time twelvemonth, eſpecially if they are duly watered in dry weather, and may then be tranſplanted, either in a nurſery for a year to get ſtrength, or to the place where they are to remain for good, which ſhould be in a warm light ſoil and a ſheltered ſituation, where they will endure the cold of our ordinary winters very well; and if their roots are covered with ſtraw, Fern, Peas-haulm, or any other light covering, there will be no danger of their being deſtroyed by the froſt.

[3, 4, 11 and 22 muſt be kept in the bark ſtove.

   Legumes smooth? leaflets elliptic, cusped, stalk hispid, scabrous.

DESCRIPTIONS, &c.

These are tall-growing, perennial, herbaceous plants, with the stalks somewhat woody at bottom. The stipules are distinct from the petiole. The flowers in a head or spike, from the axils and at the ends of the branches. The seed-vessel a legume or pod, smooth, hairy, or prickly.

1. The common petiole has a distinct rim with a nerve along the middle of it. The leaflets are lanceolate-ovate. The stipules ensiform. The flowers in a roundish head[a]. According to Gmelin, the stipules are small and oblong, not ensiform.]

The stalks and leaves of this are very like those of the second, but the flowers are produced in shoter spikes, and the pods are very short, broad at their base, end in acute points, and are armed with sharp prickles. It flowers from april to june, and in warm seasons will perfect seeds in England.

[Native of monte Gargano in Apulia, of the northern provinces in China, and of Tartary.—Cultivated by Gerarde in 1596.]

2. The roots run very deep into the ground, and creep to a considerable distance, especially where they stand long unremoved. From these arise strong herbaceous stalks, four or five feet high. Leaves composed of four or five pairs of ovate leaflets, terminated by an odd one: these and the stalks are clammy, and of a dark green. Flowers in axillary spikes, standing erect, and of a pale blue colour. Pods short, containing two or three seeds.

[The common petiole is extended beyond the uppermost pair of leaflets; the spikes are oblong, and the flowers distant[b].—Native of the South of Europe, in France, Spain and Italy; also of China. Cultivated in China, Germany, England, &c. Here particularly about Pontefract in Yorkshire, Worksop in Nottinghamshire, and Godalmin in Surry;] and of late years there has been much raised in the gardens near London. [It appears from Turner's herbal that it was cultivated in England in 1562: and Stow informs us that "the planting and "growing of Licorish begun about the first year of "Queen Elisabeth." (1558.) Gerarde (1597) relates, that he had plenty in his garden; and that the poor people of the north parts of England manured it with great diligence, whereby they obtained great plenty thereof. Ray affirms that the Liquorice root of English produce is superior to the foreign. The quantity now exported from Spain is said to be annually not less than 4000 quintals, or nearly 200 tons, a considerable part of which is supposed to be purchased by the porter brewers in London[c].]

3. This has much the appearance of the two foregoing sorts, but the pods are hairy and longer. Native of the Levant, whence the seeds were sent to Paris by Tournefort.

[Cultivated in 1739, by Mr. Miller[d].

4. This has rather the air of an *Astragalus*. Root slender and very long, extremely sweet, especially in the spring. The flower pale violet. Discovered by Pallas, on sandy hills between the Wolga and the Jaick[e].

Liquorice root contains a great quantity of saccharine matter, with some proportion of mucilage. Lightly boiled in a little water it gives out nearly all its sweetness: the decoction, pressed through a strainer, and inspissated with a gentle heat till it will no longer stick to the fingers, affords a better extract than that brought from abroad, and its quantity amounts to near half the weight of the root. Rectified spirit takes up the sweet matter of the Liquorice equally with water; and as it dissolves much less of the insipid mucilage, the spirituous tincture and extract are sweeter than the watery. Liquorice is in common use as a pectoral or emollient in catarrhal defluctions on the breast, coughs, hoarsenesses, &c. The infusions or extracts are commodious vehicles for other medicines[f].]

PROPAGATION AND CULTURE.

2. This plant delights in a light sandy soil, which should be three feet deep at least, for the goodness of Liquorice consists in the length of the roots; the ground in which you intend to plant Liquorice, should be well dug and dunged the year before you plant it, that the dung may be perfectly rotted, and mixed with the earth, otherwise it will be apt to stop the roots from running down; and before you plant it, the ground should be dug three spades deep, and laid very light; when your ground is thus well prepared, you should furnish yourself with fresh plants taken from the sides or heads of the old roots, observing that they have a good bud or eye, otherwise

[a] Lin. spec. [b] Towns. Spain. 2. 356. [c] Hort. kew. [d] Lina. suppl. [e] Lewis & Woodv.

they are ſubject to miſcarry; theſe plants ſhould be about ten inches long, and perfectly ſound.

The beſt ſeaſon for planting them is in the beginning or middle of march, which muſt be done in the following manner, viz. Firſt ſtrain a line acroſs the ground in which you would plant them, then with a long dibble made on purpoſe, put in the ſhoot, ſo that the whole plant may be ſet ſtraight into the ground, with the head about an inch under the ſurface in a ſtraight line, about a foot aſunder, or more, in the rows, and two feet diſtance row from row; and after having finiſhed the whole ſpot of ground, you may ſow a thin crop of Onions, which being plants that do not root deep into the ground, nor ſpread much above, will do the Liquorice no damage the firſt year; for the Liquorice will not ſhoot very high the firſt ſeaſon, and the hoeing of the Onions will alſo keep the ground clear from weeds; but in doing of this you muſt be careful not to cut off the top ſhoots of the Liquorice plants when they appear above ground, which would greatly injure them; and alſo obſerve to cut up all the Onions which grow near the heads of the Liquorice; and after your Onions are pulled up, you ſhould carefully hoe and clean the ground from weeds; and in october, when the ſhoots of the Liquorice are decayed, you ſhould ſpread a little very rotten dung upon the ſurface of the ground, which will prevent the weeds from growing during the winter, and the rain will waſh the virtue of the dung into the ground, which will greatly improve the plants.

In the beginning of march following you ſhould ſlightly dig the ground between the rows of Liquorice, burying the remaining part of the dung; but in doing of this, you ſhould be very careful not to cut the roots. The ſtirring of the ground will not only preſerve it clean from weeds a long time, but alſo greatly ſtrengthen the plants.

The diſtance which I have allowed for planting theſe plants, will, I doubt not, by ſome, be thought too great; but in anſwer to that, I would only obſerve, that as the largeneſs of the roots is the chief advantage to the planter, ſo the only method to obtain this, is by giving them room; and beſides, this will give a greater liberty to ſtir and dreſs the ground, which is of great ſervice to Liquorice; and if the plantation deſigned were to be of an extraordinary bigneſs, I would adviſe the rows to be made at leaſt three feet diſtant, whereby it will be eaſy to ſtir the ground with a breaſt plough, which will greatly leſſen the expence of labour.

Theſe plants ſhould remain three years from the time of planting, when they will be fit to take up for uſe, which ſhould not be done until the ſtalks are perfectly decayed; for when it is taken up too ſoon, it is ſubject to ſhrink greatly, and loſe of its weight.

The ground near London being rich, increaſes the bulk of the root very faſt; but when it is taken up, it appears of a very dark colour, and not near ſo ſightly as that which grows upon a ſandy ſoil in an open country.

DESCRIPTION, *&c.*

A tree, with round ſtiff upright branches. Leaves oppoſite, petioled, ovate, tomentoſe underneath, having frequently a ſhorter ſharp lobe on each ſide. Spines axillary, oppoſite, horizontal, pubeſcent at the tip, the length of the petioles. Flowers from the end of the tender twigs, on peduncles[1]. The fruit is a berried drupe, the ſize of Jujubes, black and ſmooth: the ſhell bony, thick at top, with two ſmall lateral lobes; remarkably acuminate at bottom. In each of the two upper cells is a ſingle ſeed, thickiſh, convex on one ſide, and flattiſh on the other; whitiſh or pale ſtraw-colour, with a ſmall umbilical caruncle below the top: there is no *albumen* or white, but the embryo is of the ſame form with the ſeed: the cotyledons or ſeed-lobes are elliptic, fleſhy and thickiſh[2].

The *Cumbula* of the *hortus malabaricus* 1. *p.* 75. *t.* 41. is by no means *Bignonia Catalpa*, but a genuine ſpecies of *Gmelina*, as abundantly appears from the fruit[3].

Jamboſa ſilveſtris parvifolia of Rumphius (*t.* 129. *t.* 40.) cited by Linneus as this ſpecies, is a ſpecies of Eugenia[4].

62. Gnaphalium japonicum.

Lin. ſyſt. 749. *Thunb. jap.* 311.

Herbaceous: upright; leaves linear-ſword-ſhaped, ſnowy-white underneath, heads terminating.

63. Gnaphalium trinerve.

Forſk. fl. auſtr. n. 289.

Shrubby: leaves ſeſſile, lanceolate, three-nerved, ſilvery-white underneath, panicle corymbed, terminating, looſe,

64. Gnaphalium lanatum.

Forſk. fl. auſtr. n. 290.

Herbaceous; woolly: leaves linear-oblong, callous-mucronate at the tip, corymb contracted, ſtalk very ſimple.

65. Gnaphalium involucratum.

Forſk. fl. auſtr. n. 291.

Herbaceous: leaves linear, elongate, mucronate, tomentoſe underneath; head terminating, leafy.

66. Gnaphalium ſinuatum.

Lour. cochinch. 497.

Herbaceous: branches aſſurgent, leaves ovate-lanceolate, ſinuate, toothed, hairy on both ſides.

DESCRIPTIONS, *&c.*

The numerous ſpecies of this genus are either Underſhrubs or Herbs. The leaves are placed alternately, and are for the moſt part hoary. The flowers uſually terminate the ſtem and branches in globes or corymbs. The calyx is permanent, with yellow or white ſcales.—The Filagos are ſcarcely diſtinct from the Gnaphaliums, conſidered as a natural genus.

1. *Stem* the thickneſs of a finger, and tomentoſe. *Leaves* ſharpiſh, without veins, white, with nap on both ſides. *Corymb* terminating, without a common peduncle; there is one leaf, and uſually only one flower to each peduncle. *Flowers* globular, with calyxes as large as the outer joint of a finger, conſiſting of imbricate, roundiſh, ſcarioſe, concave, obtuſe, ſmooth, purpliſh ſcales *.

Native of the Cape of Good Hope: as are alſo the eleven ſucceeding ſpecies.

2. This is a ſhrub the height of a man, determinately branched. *Leaves* reſembling thoſe of Roſemary, crowded, ſtrict, acute, naked, underneath tomentoſe, as are alſo the branches; with ſmaller leaves alternate, remote. *Corymb* very much crowded:

* Linn. mant.

calyxes

calyxes white, with a cinereous pile [1].—It flowers moſt part of the year, and was introduced in 1770, by Mr. William Malcolm [2].

3. Branches round, ſimple, tomentoſe. Leaves alternate, obtuſe, ſhortly acuminate; beneath tomentoſe-woolly, white, five-nerved; green above, tomentoſe, ſomewhat woolly; two inches long, frequent: the upper ones lanceolate, acute, ſmaller. Flowers large, roundiſh, ſnow-white, in roundiſh, heaped, ſolitary cymes, on long, tomentoſe, ſcaly peduncles [3].

Introduced in 1787, by Mr. Francis Maſſon [4].

4. *Stem* the thickneſs of a finger, determinately branched, villoſe. *Leaves* crowded, three-nerved, obtuſe, mucronate, the ſize of the outer joint of the thumb, tomentoſe underneath, villoſe above but at length becoming naked. *Flowers* terminating, and heaped into a ſeſſile head. *Calyx* yellow on the outſide, but white within.

It approaches to the foregoing ſpecies; but the flowers are larger, the leaves not narrowed towards the top, the baſe of flowers not on a peduncled common peduncle, the ſtem woody and ſtiff [5].

5. Large among the greater ſpecies. Root-leaves many, quite entire: ſtem leaves attenuated. Peduncle elongated, tomentoſe, terminated by a compound, many-flowered cyme. Flowers ſmall: outer calyxes red, inner yellow [6].

6. Large. Stem cloathed with leaves up to the cyme. It is remarkable for a little, lanceolate, ſcarioſe membrane, terminating the leaf [7].

7. *Stems* woody, with villoſe branches. *Leaves* very tomentoſe. *Branchlets* from the upper axils of the leaves. *Corymb* terminating without a common peduncle: partial pedicels longer than the leaf at their baſe; the lateral ones longer than the middle one; bearing at the tip in form of a head many ſeſſile, hirſute calyxes, dilated at the edge into a round, ſmooth, ſnow white ray [8].

8. Stems underſhrubby. Leaves woolly-tomentoſe underneath. Common peduncles elongated. Calyxes glomerate, with ſix lower ſcales, ſhorter and fleſh-coloured, twelve inner white, blunt. Flowers in a kind of umbel, with about five florets in each [9].

9. Stem erect, round, pubeſcent; branches patulous, ſimple, alternate or ſomewhat heaped, ſlightly tomentoſe. Leaves round above, ſmooth, ſomewhat concave underneath, tomentoſe, rolled back on the edge, ſeſſile, ſcattered, frequent, ſpreading, having ſmaller leaves in bundles in their axils. Flowers ſeſſile, in terminating, multifid, ſeſſile umbels, white-tomentoſe; divided into partial ſpiked umbels. Bractes linear-acuminate, ſmall, ſubtomentoſe [10].

This varies with leaves ſharp or prickly like thoſe of Juniper. Florets three or more, ſeldom five or ſix [11].

10. This is a wretched plant with poor leaves and flowers. The branches are wand-like, rigid, unequal. The leaves remote and very minute. The flowers terminating, few, ſubſeſſile. The outer calyx conſiſts of greeniſh-aſh-coloured, ſubtomentoſe leaflets; the inner of ſmooth, oblong, fleſh-coloured ſcales [12].

Introduced 1774, by Mr. Maſſon. It flowers from march to auguſt [13].

11. The calyxes are entirely ſmooth, ferruginous without, whitiſh within. Leaves ſubulate, naked, tomentoſe underneath, with the edge rolled back [14].

Stem aſh-coloured, round, ſubtomentoſe; branches leafy, white tomentoſe: branchlets determinate, umbelled, erect, each loaded in the middle with other ſhort aggregate branchlets. Leaves linear-ſubulate, mucronate-hooked, convex above, ſmooth, white-tomentoſe underneath, rolled back on the edge, ſeſſile, ſcattered, approximating, two lines in length, ſpreading very much. Flowers pedicelled, in roundiſh cloſe corymbs at the ends of the branchlets, tomentoſe, naked, ſubpeduncled [15].

This, and all the foregoing ſpecies, with the next following, are natives of the Cape of Good Hope.

12. Branches a ſpan long, erect, ſimple, round, ſlightly tomentoſe, aſh-coloured. Leaves approximating, convex underneath, channelled above, mucronate with a ſlender pungent prickle, tomentoſe on both ſides with wool preſſed cloſe, ſeſſile, ſcarcely an inch long, from erect ſpreading. Flowers ſix, large, in panicles, terminating, contracted, on one-flowered tomentoſe peduncles [16].

13. Stem about three feet high, with long ſlender irregular branches, the lower ones having blunt leaves, two inches and a half long, and an eighth of an inch broad at the end; thoſe on the flower-ſtalks are very narrow, and end in acute points; the whole plant is very woolly. Flowers terminating in a compound corymb: calyxes at firſt ſilvery, but turning to a yellow ſulphur-colour. If they are gathered before the flowers are much opened, the heads will continue in beauty many years, if kept from air and duſt.

[According to Haller, all the flowers are androgynous. Calyx cylindric, three lines long, ſhining, ſmooth; the ſcales convex, blunt, elliptic, ſeldom containing more than fourteen florets [17].

The flowers have been formerly recommended as attenuants, diſcutients, and diaphoretics, but are not uſed in modern practice.

Native of Germany, France, Spain, and Iſtria.—Cultivated in 1629 [18].

By old writers it is called *Gold-flower*, *God's-flower*, *Goldilocks*, and *Golden Stoechas*: by Ray *Narrow-leaved Goldylocks* or *Caſſidony*.]

14. Stem and leaves woolly; the former a foot high, ſending out a few ſide branches, terminated by a compound corymb, the heads of which are ſmall, of a gold colour, changing to red as they fade.

[The native place of growth is not known.—It was cultivated in 1768, by Mr. Miller.

15. The whole plant is hoary. Branches ſcarcely a ſpan long and round. Leaves blunt at top and three-toothed, thick and veined. Flowers at the ends of the branchlets, few, ſmall, ſhining, in oblong heads.

16. This is an elegant plant, ſuffruticoſe, ſoft and ſilky, yellow, much branched, with procumbent, ſimple, pubeſcent runners. Leaves very frequent, ſoft, entire, yellow. Flowers terminating, very many, in a cloſe compact head, each on ſhort pedicels [19].

17. Branches filiform, a foot or more in length, round, white-tomentoſe, patulous, ſomewhat branched. Branchlets alternate, ſimple, patulous, white-tomentoſe, aſcending. Leaves alternate, blunt and ſerrulate at top, linear and ſeſſile at bottom, ſtem-claſping with rounded angles, white-tomentoſe underneath, greeniſh-ſubtomentoſe above, an inch long, ſpreading. Cymes terminating, looſe, on long peduncles, tomentoſe, leafleſs; branches ſimple and branchletted; flowers large, peduncled [20].

Introduced in 1774, by Mr. Francis Maſſon. It flowers from auguſt to january [21].

18. Related very nearly to the foregoing, according to Linneus, but it is not in his herbarium, and the plant in hort. cliff. is Stæhelina aboreſcens.

19. Stem a foot high, proliferous-branched, perennial except the proliferous branch. Leaves wider at the end, blunt, covered with a very thick down, ſtiffiſh, towards the flowers gradually narrower. Flowers numerous. Calyxes pale yellow. Corollas of a deeper colour. The florets before they open appear white [22].—Native of Majorca and Minorca. Introduced in 1774, by Monſ. Richard. It flowers from july to ſeptember [23].

[19] Burm. [20] Bergius. [21] Hort. kew. [22] Linn. mant.
[23] Hort. kew.

20. A ſhrub of four feet in height; the branches pubeſcent. Leaves alternate, ſomewhat crowded, tomentoſe, aſh-coloured, when young very white. Corymbs terminating, cloſe, roundiſh, on very ſhort peduncles. Calyx rude, white with down: ſcales ſharpiſh at the end, browniſh about the edge. Flowers gold-coloured. It differs from the foregoing, in having the leaves by no means narrowed at the baſe [b].

Introduced about 1772. It flowers from june to auguſt [c].

21. Stem creeping, rooting, perennial, perfectly ſimple, filiform, angular, four feet high. Branches alternate, two inches in length, bearing both leaves and flowers. Leaves filiform, naked, lax, ſomewhat viſcid, alternate, patulous, acute. Heads of flowers terminating and glomerate. Calyxes blunt, containing few flowers, yelloviſh, the ſize of hemp ſeeds [d].

22. In the herb this bears a ſtrong reſemblance to G. mucronatum (n. 9.): but it differs in having a regular umbel, larger flowers, and the ſcales of the calyx a beautiful red, in which laſt circumſtance it reſembles a Xeranthemum [e].

23. This ſpecies is eaſily known by the ſtiff briſtles on its acerоſe leaves, and by its aggregate flowers [f].

Theſe nine ſpecies, except the 19th, are natives of the Cape of Good Hope.

24. Herb branched, diffuſed, a ſpan in length, tomentoſe all over: calyxes very long, imbricate, with equal, ovate, bluntiſh ſcales.

Native of the Cape [g].]

25. Stem ſeldom riſing more than three or four inches high, and putting out many heads. Leaves narrow, woolly on both ſides, and coming out without order. Flower-ſtems eight or ten inches high, with narrow hoary leaves all the way, terminated by a compound corymb of bright yellow flowers in large heads, coming out in may, and continuing in ſucceſſion moſt part of the ſummer. It has been long in Portugal, where in the winter ſeaſon they ornament the churches with the flowers.

[This is improperly called Gn. orientale, and Eaſtern Everlaſting, for it is ſuppoſed to be a native of Africa.—Parkinſon, who calls it *Golden Flower-gentle*, cultivated it in 1629.]

β. The ſhrubby or narrow-leaved ſort grows naturally at the Cape of Good Hope. This differs from the other in riſing with ſtalks four or five feet high, dividing into many branches, having long narrow leaves placed alternately; the corymb is looſe, with the flowers on long pedicels; whereas thoſe of the other are compact [h].

[26. This is an annual hoary plant, with an oblong root. Stem upright, a foot or more in height, white with down. Leaves alternate, an inch long, and three or four lines wide, half-ſtem-claſping, quite entire, white with down on both ſides, blunt and frequently recurved a little at the tip, the edges rolled back. The ſhining yellow heads of flowers are two lines in length and breadth: the calycine ſcales are ovate, blunt, and lemon-coloured, as are alſo the corollets [i].

Native of Scania, Denmark, Germany, in dry ſandy paſtures and hills, flowering from july to ſeptember. Alſo in Japan, where it is uſed for Moxa, and as Tobacco; by way ſides and in ditches, flowering from december to april [k].

It was formerly much recommended in dyſenteries, &c. but is now diſuſed. It is ſuppoſed to preſerve woollen clothes from the moth [l].]

27. Stem ſlender, ſending out many lateral branches below, with very narrow leaves, hoary on their under ſide. The flowers are produced in a compound corymb at the ends of the branches; at their firſt appearance they are of a pale red, but afterwards change to a gold colour; the calyxes are ſmall, and dry like the other ſpecies of Everlaſting.

Native of the Cape of Good Hope.

[It flowers from the end of june to the beginning of auguſt. Cultivated in 1732 by James Sherard, M. D. at Eltham [m].

28. Stalk a foot high, tomentoſe. Leaves lanceolate, hirſute on both ſides. Corymb terminating, with above fifty flowers in it: peduncles ſubdichotomous, elongated: braCtes ſcarioſe, ovate, pale: calyxes ſmooth and even, pale; with the lower ſcales purpliſh: corollas yellow.

Native of the Cape of Good Hope, where it was found by Thunberg [n].

29. Stem aſh-coloured tomentoſe, diffuſed, erect, ſcarcely a foot high. Branches alternate, wand-like, ſimple, tomentoſe, erect. Leaves alternate, linear-wedge-ſhaped, ſharpiſh, ſeſſile, greeniſh-aſh-coloured above, aſh-coloured and more tomentoſe underneath, the length of the internodes, ſpreading and bent down. Flowers ſmalliſh, glomerate-corymbed, ſubſeſſile. Corymbs alternate, panicled, peduncled, at the ends of the branches.

Native of the Cape of Good Hope [o].

30. The flowers are entirely of a gold colour, and ſmooth with blunt ſcales. Calyxes ſmooth and even [p]. Perennial, about eighteen inches in height; ſtalks woody cylindric; leaves frequent, ſhaped as in *Geniſta tinctoria*, ſtiffiſh, concave, bright green and ſhining on the upper ſurface; on the flowering ſtems they are more ſharp pointed. Flowers very numerous, ſmall, oblong. Theſe and the leaves, when rubbed, emit an odour, like that of Southern-wood [q].

Native of the Cape of Good Hope. It was cultivated in 1732, by James Sherard, M. D.; and flowers from april to auguſt [r].

31. Root-leaves lanceolate-ovate, by no means tomentoſe, ſcabrous about the edge. Stalk ſimple, a foot high, having ſmaller leaves of a more lanceolate ſhape at bottom, and naked at top. Flowers golden in a compound corymb [s]. Receptacle naked, and therefore not of the genus Athanaſia [t]. Bergius however makes the receptacle chaffy; the chaffs lanceolate, ſubemarginate, ſcarioſe, a little longer than the germ. Gærtner ſeparates this and ſome other Gnaphaliums under the name of Anaxeton, on account of the receptacle being villoſe or chaffy only towards the circumference; and the down being ſimple or capillary.

Native of the Cape, and perennial.

32. This is an annual plant, and very woolly. Stalks many, upright, a foot or eighteen inches in height. Leaves alternate, quite entire, very ſoft, waved, and convolute. Calyxes whitiſh-yellow, ſoft, with ovate-lanceolate ſcales. Florets many female in the circumference, and a few androgynous in the centre.—It is higher than G. arenarium (n. 26.): the ſtalks are weaker and round; the leaves narrower and longer: the flowers more glomerate [u].

Native of the South of France, Spain, Portugal, Switzerland, Germany, the iſland of Jerſey; in ſandy grounds, and on dry banks and walls. Alſo of New Caledonia. It flowers from july to ſeptember.]

There is a variety of this with narrower leaves, not quite ſo woolly; the ſtalks riſe higher, and are more branched; the flowers grow in cloſe bunches on the top of the ſtalks, and are of a pale yellow colour.

[33. Shrubby. Native of Jamaica [x].

34. Stalk herbaceous, a foot and a half in height, branched, diffuſed with elongated branches. Leaves alternate, ſpatulate except the upper ones which are lanceolate, green and almoſt naked on the upper ſurface. Peduncles terminating, very long, tomentoſe, whitiſh, with a very few leaves extremely

[a] Linn. mant. and ſyſt. [b] Hort. kew. [c] Linn. mant. [d] Linn. ſuppl. [e] Ibid. [f] Linn. amoen. [g] Milk &c. [h] Pollich. [i] Thunberg. [k] Krocker, [l] Hort. kew. [m] Linn. ſuppl. [n] Bergius. narrow, terminated by a glomerate cyme. Calyx yellowiſh.

Native of the Cape of Good Hope [y].]

35. Lower leaves oblong and blunt. Stems about three feet high, dividing into many irregular branches, on which are oblong blunt leaves, hoary on their under ſide, but of a dark green above, decurrent. Stems terminated by a compound corymb of flowers, cloſely joined together, of a bright gold colour, but ſmall, and changing to a darker colour as they fade. Native of the Cape.

[Cultivated 1691, in the royal garden at Hampton-court [z].]

36. Under leaves ſpreading near the ground, woolly on their under ſide. Stems about ſix inches high, with lanceolate acute leaves, woolly terminated by a large corymb of flowers ſitting very cloſe, and of a fine red colour.

Native of Egypt and Paleſtine.

37. This is an annual plant, ſending out many oblong blunt leaves near the root. Stems a foot and half high. Leaves alternate, when handled emitting a very rank odour. Stems terminated by a corymb of flowers, which have large ſilvery calyxes, that will retain their beauty ſeveral years.

Native of the Cape.

[It varies with golden calyxes [a]. Cultivated in 1692, by Mr. George London, at Brompton [b].]

38. Annual. Bottom-leaves oblong, a little waved, hoary on their under ſide. Stems about a foot high. The whole plant has a diſagreeable odour. The flowers in a terminating corymb: they are white and appear in july.

Native of the Cape of Good Hope, and alſo of North America.

[Cultivated in 1732, by James Sherard, M. D. at Eltham [c].

39. Annual. Seldom riſes above ſix or nine inches in height. Flowers yellowiſh, and diſpoſed pretty thick about the top of the ſtalk, which puts on the appearance of a ſhorter ſpike [d].

Native of Jamaica, in the coldeſt mountains of Liguanea.

40. Perennial. Stalks ſimple, hardiſh, tomentoſe, throwing out ſmall branches from the axils; theſe, as well as the whole plant, are very white. The corymbs are leafleſs. The calyxes are white, naked, not ovate-lanceolate as in *Gn. patulum*, but plaited and waved.

Native of the Cape of Good Hope [e].

41. Perennial. Stalks wand-like, branched, tomentoſe. Leaves blunt, tomentoſe on both ſides, but quite white underneath, a little waved, ſpreading, reflex. Corymb compound, terminating, ſeſſile.—Native of the Cape of Good Hope [f].

Introduced in 1774, by Mr. Francis Maſſon.

42. Stalks aſcending, ſimple, ſcarcely a foot high, very tomentoſe. Leaves blunt. Flowers terminating, crowded. Calycine ſcales naked, purple or white, hirſute at the baſe.

Native of the Cape [g].

43. Stalks ſeveral, half a foot in height. Flowers glomerate. Calyxes ſmooth, conſiſting of numerous, ovate ſcales, which ſpread out quite flat as ſoon as the time of flowering is paſt, and are purple within, with ſnow-white tips.

Native of the Cape [h].]

44. This is an annual plant, with woolly obtuſe leaves. Stems ſingle, about nine inches high. Flowers in ſpikes from the ſide of the ſtalks, of a dirty white colour.

[Stalk hairy, branched, upright. Leaves bowed back, almoſt naked. Flowers conglobate, unequal, ſubſeſſile. Calyxes white, ſharp. Corollas yellow [i].

Native of Virginia, Penſylvania, and New-England. Cultivated in 1699, by Mr. Jacob Bobart, in the Oxford Garden [k].]

[y] Linn. mant. [z] Hort. kew. from Plukenet. [a] Linn. ſyſt. Hort. kew. from Plukenet and Morriſon. [b] Dill. elth. [c] Browne. [d] Linn. ſpec. [e] Ibid. [f] Ibid. [g] Linn. amoen. and ſpec. [h] Linn. ſpec. [i] Hort. kew. from Mor. hiſt. [k]

45. Root perennial, creeping, and ſpreading far, ſo as to become a troubleſome weed. [Stalks extremely downy, white. Leaves, numerous, long, ſeſſile, growing without order round the ſtem, entire at the edges, dark green, naked above, beneath covered with a thick down, and whitiſh. The flowering branches form a broad flat bunch: each branch contains numerous crowded heads, on ſhort, branched, downy peduncles, but the middle ones ſeſſile: ſcales of the calyx bluntly ovate, white, not downy. Seed crowned with a ſeſſile feather of few ſimple rays, as long as the calyx. Haller ſays that the flowers are all hermaphrodite, but afterwards adds, that a few females are ſometimes intermixed with them [l].

Native of North America, *where it grows in* vaſt quantities in uncultivated fields, glades, hills, &c. and is called *Life Everlaſting*; becauſe the ſilvery heads, properly dried, will keep their beauty long without changing [m]. It is alſo found in Kamtſchatka: and with us in England; having been obſerved near Bocking in Eſſex by Mr. Dale; and on the banks of Rymny river, for the ſpace of twelve miles by Mr. Lhwyd. None of our old herbariſts mention its being found wild in this iſland, but it has been long known in our gardens. It flowers from july to ſeptember.

A decoction of the flowers and ſtalks is uſed in America, to foment the limbs, for pains and bruiſes [n].]

46. Perennial. From the main ſtalk come out runners, which take root in the ground. Stem-leaves narrower, woolly, alternate. Flowers in a terminating corymb, white and ſmall, appearing in june and july.—Native of North America.

[Linnæus obſerves, that it has altogether the air of the foregoing. He had ſeen only the female, and doubted whether it might not be a variety only of the next ſpecies.

It was cultivated by Mr. Miller in 1759 [o].

47. Root woody, brown, ſtrikes deep, throwing out a few rigid fibres; from the crown ariſe ſeveral creeping runners. The root-leaves form a thick tuft, and are oval at the extremity, tapering into a long footſtalk; they are green and ſlightly hairy above, beneath white with a thick down. Stems erect, ſimple, from two or three to ſix or ſeven inches high, white, downy, cloathed with numerous ſemiamplexicaul linear leaves, green above, white and downy beneath. Flowering heads three to eight crown the ſtem in a cloſe bunch, on ſhort peduncles; ſcales of the calyx blunt, the outer ones ſhort, green covered with down, the inner widening, upwards, long, ſmooth, white, ſhining, frequently tinged with purple. The calyxes bearing female flowers are cylindrical; the ſeed ſhort, crowned by a ſeſſile down with ſimple rays, longer than the calyx. The calyxes bearing hermaphrodite flowers are globular, ſhorter, and the feather does not exceed the calyx. Haller ſuſpects that the hermaphrodite flowers are barren. It is rare that any ripe ſeed is produced, ſuch being the caſe with many plants that creep by the roots. The female heads often have imperfect ſeeds; the hermaphrodites none at all. Not one of the figures are good [p].

Native of moſt parts of Europe, on open downs. With us on Newmarket heath and Gogmagog hills, Canham heath near Bury, Swaffham and Stratton heaths in Norfolk, in Cornwall, Wales, on Bernack and Wittering heaths, in the northern counties, and Scotland. Flowering in may and june.

48. Root perennial. Stalk entirely ſimple, ſhorter than a finger, with three or four lanceolate leaves. Root-leaves lanceolate-wedge-ſhaped, the upper ſurface green, ſmooth and even, the under white with a ſtreaked nap, ſo that the edge even of the upper ſurface appears white. It has runners at the root like the foregoing. Flowers terminating, few, crowded, without leaves. Calyx cylindrical, ſwell-

[l] Woodw. Mſs. [m] Kalm. [n] Ibid. [o] Hort. kew. [p] Woodw. Mſs.

ing at the base; the scales membranaceous at the tip, lanceolate, sharp, upright [a].—Linnæus has observed only the female flowers, and doubts whether it may not be a variety of *Gn. dioicum*.

The colour of the flower is by no means shining in this; otherwise it has the appearance of the foregoing, the size, stalks, flowers, and runners; but the leaves are narrower, the calycine scales lanceolate, villose at the base, brown at the tip and edge [b].

Native of the Lapland Alps, and of Switzerland. Introduced in 1775, by Drs. Pitcairn and Fothergill [c].

49. Perennial. Stalk half a foot high, tomentose. Leaves ending in the petioles, broader at top, sharp, toothed, tomentose, white. Corymbs compound terminating the branches. Flowers small: calycine scales ovate, brown, those surrounding the disk dilated, round and white; so that the heads are brown with a white crown [d].

Native of the East Indies, and Cochinchina.

50. Annual. Stalks from a span to a foot in height, sometimes upright and unbranched, sometimes reclining and putting out a few branches, slender, tomentose. Leaves from green becoming hoary; those next the root broader, and (according to the figure) waved about the edge, quickly drying away; stalk-leaves narrower, till they become linear among the flowers, the heads of which are short and purplish. It flowers in summer and autumn [e].

Native of Carolina and Virginia. Cultivated in the Eltham garden before 1732.

51. Stalks prostrate, filiform, hardish, with alternate, upright branches. Leaves alternate, sessile, mucronate, the upper surface naked but not smooth. Corymb or umbel terminating, and very short; flowers peduncled. Calyx green, with a short, white ray.

Native of the Cape of Good Hope, Montin [f].

52. This is a biennial plant. In woods one stem from twelve to eighteen inches high generally grows from the root. In open ground the root-leaves form a thick tuft, and from among them arise several shorter stems, sometimes not more than three inches high, at first often declining, but very soon ascending. Root-leaves long, of a very narrow linear-lanceolate form, green and hairy above, white and thickly downy beneath. Stalk simple, white, downy, cloathed with numerous linear leaves, half embracing the stalk, green and hairy above, white and downy beneath, like the others. Flowers in a long spike, composed of very short branches, bearing from one to five or more flowers; the lower branches somewhat distant, the upper crowded; beneath each a leaf, similar to, but smaller than the stem-leaves. Flowering heads very small; scales of the calyx bluntly oval, greenish at the base, yellowish brown upwards, smooth with shining margins; exterior short, interior as long as the florets. Seeds minute, crowned with a sessile feather, having simple rays as long as the calyx [g]. Female flowers numerous; hermaphrodites four or five [h].

Native of the north of Europe; β. Common in Europe and Highlands of Scotland. In Britain it has been observed in Norwood, Surry; on Hampstead heath, and in the woods thereabouts; near Charlton; about Harefield; in Gamlingay park, Cambridgeshire; in Armingdale wood near Norwich; on Naseby field, and Thorp-Malsor in Northamptonshire; in rough pastures near Fladbury in Worcestershire; on a sandy heath, a mile from Shiffnall, on the road to Wolverhampton; on the banks of the canal in the parish of Cosely, Warwickshire; on the great island in Winander mere. They both flower in august.

53. Stems several, ascending, a finger's length, smooth, covered with leaves and flowers. Leaves unequal, acute, smooth above, subtomentose underneath, the upper ones longest. Flowers from all the axils from top to bottom of the stem, glomerate, minute. Calycine scales scarious, ferruginous, shining, ovate-lanceolate.

Native of Egypt [i].

54. Annual. Stalk a span high, upright, without any branch. Leaves very narrow, an inch in length. Flowers in whorls over the whole stalk, and sessile. The whole plant, and even the flowers are ash-coloured. It is related to the foregoing.

Native of the Cape of Good Hope.

55. Stalks filiform, very many, decumbent, diffused, somewhat branching. Leaves sessile, almost naked. Flowers flattish, and cohering, in circles. Calyx concealed by a very thick white nap. Corollas small, surrounded by nap.

Native of the Cape.

56. Perennial. Leaves three or four at the root, elliptic, bluntish. Scape twice as long as the leaves, hairy. Flowers terminating. Calyxes roundish, villose, white about the edge.

Native of the Cape.

57. Stalks prostrate, filiform. Leaves white with a fine nap, shining, crowded. Flowers in a terminating, fastigiate, leafless corymb. Calyx ovate, smooth and even, testaceous and scariose. Florets many in a small calyx:

Native of the Cape [k]. Introduced 1787, by Masson [l].

58. Perennial. Stalks a span high, upright, villose, flowering at the end, branched, hairy. Leaves alternate, narrow-lanceolate, with a very thick nap on them. Flowers in corymbs, heaped. Peduncles leafy. The flowers proceed as it were from the ray of a full calyx—Native of the Cape [m].

59. This resembles *G. sylvaticum* very much, but it is low, and the stalk is decumbent whilst the plant is in flower [n].

Perennial.—Root-leaves in tufts, half or three quarters of an inch long, narrow linear-lanceolate, slightly hairy above, downy beneath but greenish. Stem two or three inches high, with two or three longer and narrower sessile leaves. Flowering heads single, not more than three or four, larger than in *Gn. sylvaticum*, alternate, either sessile or on short downy peduncles, from the axils of the upper leaves, which are not longer than the heads. Scales of the calyx lanceolate, with a green dorsal line at the base, and brownish-yellow shining tips and margins. Seeds elliptical, crowned with a sessile down having simple rays as long as the florets, and longer than the calyx [o]. The florets are mostly female, but a few in the centre of the disk are hermaphrodite [p].

Native of the Swiss and Italian Alps; and the tops of the highland mountains in Scotland: found on Ben Lomond, by Dr. J. E. Smith; and five miles from Fort George, on the west side of the road to Aberdeen. It flowers in july and august.

60. Annual. Stem from three or four to seven or eight inches and even more upright, covered with thick white down, and much branched; branches spreading, lower ones often procumbent, cloathed with numerous leaves, particularly towards the summit, and these thickest and most downy. Leaves elliptical, tapering into a long footstalk, slightly downy and greenish above, more so and whitish beneath. The ends of the branches are crowded with numerous heads of nearly sessile flowers. Scales of the calyx lanceolate, smooth, brown, shining; when old blackish, almost hid in the down. Feather sessile, with few simple rays as long as the calyx [q].

Native of the greater part of Europe, in marshy places, especially where water stagnates in winter. It flowers in august.

61. Annual. Leaves spatulate, extremely hirsute. Heads leafy. Branches higher than the stalk [r].

Native of the Cape of Good Hope.

62. Root fasciculed, with small fibres, annual. Stalks one or two, simple, naked at top, white with

[a] Linn. spec. [b] Linn. suec. [c] Hort. kew. [d] Linn. suppl. [e] Linn. syst. [f] Dill. elth. [g] Linn. suppl. [h] Woodw. Mss. [i] Vahl. [k] Linn. suppl. [l] Hort. kew. [m] Woodw. Mss. [n] Haller. [o] Lion. suppl. [p] Lightfoot. [q] Woodw. Mss. [r] Linn. syst.

down,

down, a span and half in height. Root-leaves very many, drawn to a point below, sharp, entire, lax, often reflex, a palm in length and half a line in breadth; stem-leaves sessile, upright, shorter. Flowers on the stalk terminating, glomerate, sessile, purplish; the heads the size of a large pea.

Native of Japan: flowering in auguſt [a].

63, 64, 65. Native of New Zealand [t].

66. Stem four feet high, ſimple erect. Leaves large, alternate. Flowers yellow, in terminating erect panicles, the marginal ſcales of the calyx being red and membranaceous.

Native of Cochinchina [w].]

PROPAGATION AND CULTURE.

The tender ſorts, ſuch as all thoſe from the Cape, &c. 1 to 12, 15 to 24, 27 to 31, 33 to 35, 37 to 43, 51, 53 to 58, 61 to 66 Oriental Everlaſting (n. 25.) &c. may be increaſed, by ſlipping off the heads, or by cuttings, during any of the ſummer months: they ſhould be planted in a bed of light earth, (or in pots in a gentle hot-bed,) and covered with hand-glaſſes, or ſhaded with mats, obſerving to refreſh them frequently with water in ſmall quantities; theſe cuttings will put out roots in ſix or eight weeks, then plant them in pots filled with light earth, and place them in a ſhady ſituation till they have taken new root, when they may be removed to an open ſituation, and placed among other hardy exotics, till the middle or end of october; at which time they ſhould be placed under a common frame, where they may be protected from froſt, but in mild weather they ſhould be expoſed to the open air.

Common Shrubby Everlaſting (n. 13.) igneſcens (n. 14.) ſweet-ſcented (25.) ſanguineum (36.) are ſo hardy, as in very mild winters to live abroad in warm borders near walls, with little ſhelter.

Jerſey Everlaſting (n. 32.) and ſome others, will come up better from ſcattered ſeeds, than when they are ſown by art; but if the ſeeds are ſown, it muſt be ſoon after they are ripe. The plants require only to be kept clean from weeds, and to be thinned where they are too cloſe.

Gn. margaritaceum and plantagineum (n. 45 and 46.) will thrive in almoſt any ſoil and ſituation, and are eaſily propagated by their creeping roots.

As to the commom European ſorts, if the ſeeds are permitted to ſcatter, the plants will come up in the ſpring, with greater certainty than if they were ſown; but they are rather regarded as weeds than as garden plants.

GNETUM.

Lin. gen. Reich. n. 1188. *Schreb.* 1473. *Juſſ.* 406.

Claſſ. 21. 8. Monoecia Monadelphia.

Nat. order of *Piperitæ.—Urticæ* Juſſ.

GENERIC CHARACTER.

Ament of whorls remote, callous, thickened, propped underneath with a partial *calycle*. This is *peltate*, orbicular, flat, quite entire, and contains ſeſſile floſcules; the *males* at bottom, the *females* above, in the ſame whorl.

* *Males.*

CAL. *Scale* ovate, minute, coloured.

COR. none.

STAM. *Filament* ſingle, filiform, longer than the ſcale. *Anthers* double, connected.

* *Females.*

CAL. *Scale* torn, rude.

COR. none.

PIST. *Germ* ovate, immerſed in the receptacle of the whorl, the length of the ſtamens. *Style* conic, ſhort. *Stigma* trifid, acute.

PER. *Drupe* ovate, one-celled.

SEED. Nut oblong, ſtreaked.

Obs. *Rumphius has determined it to be dioecous; mine was monoecious: I have alſo ſeen an ament merely male, ſitting on its own peduncle by the female floſcule.*

ESSENTIAL CHARACTER.

MALE. An *ament* with ſcales. *Cor.* none. *Filam.* one with two anthers.

FEM. An *ament* with ſcales. *Cor.* none. *Style* with a bifid ſtigma. *Drupe* with one ſeed.

SPECIES.

1. Gnetum Gnemon.
Lin. ſyſt. 867. *Reich.* 4. 197. *mant.* 125.
Gnemon domeſtica. *Rumph. amb.* 1. 181. *t.* 71.

DESCRIPTION, *&c.*

Branches ſtiff, jointed, broader below the joints. Leaves oppoſite, petioled, lanceolate-ovate, quite entire, ſmooth and even. Aments axillary, pedunculed, in pairs from each axil, in ſmall whorls, from an orbicular, profoliate, entire bracte, callous above, in which the floſcules are immerſed, the females above, or towards the rachis, uſually ſix or ſeven in number; the males towards the edge or below.

Native of the Eaſt Indies [x]; where the leaves, male catkins and fruits are eaten, but not raw [y].

Gnemon is the vernacular name in Ternate, &c.]

GNIDIA.

Lin. gen. n. 587. *Reich.* 528. *Schreb.* 666. *Juſſ.* 77.—Struthia. *Roy.*

Claſſ. 8. 1. Octandria Monogynia.

Nat. order of *Vepreculæ.—Thymelææ* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, funnel-form, coloured: *tube* filiform, very long; *border* four-parted, flat.

COR. *Petals* four, ſeſſile, flat, ſhorter than the calyx, and inſerted into it.

STAM. *Filaments* eight, briſtle-ſhaped, erect, almoſt the length of the flower. *Anthers* ſimple.

PIST. *Germ* ovate. *Style* filiform, inſerted into the ſide of the germ, the length of the ſtamens. *Stigma* capitate, hiſpid.

PER. none. *Fruit* in the bottom of the calyx.

SEED ſingle, ovate, obliquely acute.

Obs. *Hence it differs from* Paſſerina *in the corolla only.*

ESSENTIAL CHARACTER.

Cal. funnel-form, four-cleft. *Pet.* four, inſerted into the calyx. *Seed* one, ſomewhat berried.

SPECIES.

α. *hirsuta*: leaves oblong, spatulate, hirsutely hoary; flowers smaller.
β. *glabra*: leaves oblong, alternated towards the base, almost naked; flowers larger.
Decandrous: leaves oblong, flat, quite entire; head terminating, pedunculed, involucred; flowers five-cleft.

DESCRIPTIONS, *&c.*

These are shrubby plants, except the last; natives of the Cape of Good Hope. The leaves are opposite only in one or two sorts; in the rest they are scattered. The flowers come out at the ends of the stem and branches, usually distinct, seldom in parcels together.]

1. Stem three or four feet high, with a few side-branches. Leaves acuminate, pale on their under side with a strong longitudinal nerve or keel, and resembling those of Rosemary. The flowers come out almost in whorls from between the leaves at the extremities of the branches on short peduncles.

[Calyx white. Petals lanceolate, shorter than the calyx, white. Four of the stamens are within and four without the tube[a].

Cultivated by Mr. Miller in 1768. It varies with blue flowers.

2. This is a rough, proliferous shrub. Leaves mucronate, smooth. Heads radiate with lanceolate bractes, broader than the leaf. Flowers somewhat villose on the outside. Border of the calyx smooth within, the same length with the tube. Petals smaller than the calyx, and hairy. Four of the stamens extend beyond the tube; the other four lie in the throat of it[b].

3. Stems half a foot high, unequal, roughened with four tubercles from leaves that are fallen. Leaves upright, smooth and even. Flowers naked, sessile on the villose extremity of the branch; the calyx, petals, and anthers all yellow. The floral leaves not broader than the rest. Petals oblong, acuminate. Four stamens in the throat of the tube, the other four above it[c].

Introduced in 1786, by Mr. Francis Masson[d].

4. The extremities of the twigs woolly, as in its congeners. The uppermost leaves somewhat pubescent. Four of the stamens standing out, and four in the throat of the tube. Petals small, emarginate[e].

5. Throat of the corolla crowned with eight coloured threads, the same length with the corolla itself, on the outside of the petals. Stamens four in the throat, and four within the tube[f].

Introduced in 1786, by Mr. Francis Masson[g].

6. The uppermost leaves are blood-red at the extremity. Cultivated in gardens it acquires petals. Flowers villose on the outside. Stamens, besides the four callules above the throat, are four under the throat, and four in the middle of the tube[h].

Introduced in 1788, by Masson[i].

7. Stem shrubby, with upright, round, purplish branches. Leaves very narrow and remote, smooth and even. Flowers aggregate, pedunculed. Involucre eight-leaved, lanceolate, equal, half the length of the floscules; which are sixteen in number, sessile, pubescent, hoary: tube filiform; border short, five-parted. Stamens ten, five without and five within the throat. The flower resembles that of Passerina; and perhaps it may be a species of Dais[k].

8. This is a very smooth shrub, tubercled with the scars of fallen leaves. Leaves alternate, sessile, quite entire, without apparent veins. Heads of flowers solitary, sessile. Involucre smooth. Corolla villose, with a four-parted border. Four of the filaments the length of the corolla, four shorter in the throat.—There is a variety with narrower leaves, but it is easily known by the filaments[l].

9. Found at the Cape by Thunberg.

10. Branches smooth and even, not tomentose. Leaves not prickly, convex underneath, smooth and even, patulous. Flowers from the uppermost twigs, smooth: border sharp, twice the length of the tube. Four anthers above the throat, surrounded with hairs, and four within the tube, smaller.

Observed at the Cape, by Sparrmann[m].

11. This has the habit, leaves, manner of flowering, involucre, form and hairiness of the calyx, as in *Dais cotinifolia*; the structure and situation of the parts in the flower is exactly as in this genus, but not the number. The leaves are alternate, not opposite, as in Dais. The involucre as in Dais, but five-leaved.—Found by Thouin in the island of Madagascar.

It is difficult to ascertain the limits between Dais and Gnidia; as also between Daphne and Passerina[n].]

PROPAGATION AND CULTURE.

These are usually increased by cuttings planted during the summer months in pots filled with light earth, plunged into a very moderate hot-bed, covering the pots closely with bell or hand-glasses to exclude the air, and shading them during the day. They will put out roots in six weeks, when they should be gradually inured to the open air. In winter place them in a dry airy glass-case, where they may enjoy free air in mild weather, and be protected from frost and damp air.

Vahl symb. 2. 49.
Ochna nitida. *Swartz prodr.* 67.
Leaves ovate-lanceolate, acuminate, serrate, panicles terminating, calyxes equal to the corolla.
3. Gomphia lævigata.
Vahl symb. 2. 49.
Leaves lanceolate, very obtuse, quite entire, emarginate, panicle terminating.

DESCRIPTIONS, *&c.*

1. This is very smooth. Leaves alternate, sessile, two inches long, quite entire from the base to the middle, acute at both ends, membranaceous, netted with very fine veins. Flowers in a panicle two inches long, before they unfold globular. Calycine leaflets roundish[a], permanent. Petals lanceolate. Filaments (ten *Vahl*) five, half the length of the petals. Style bristle-shaped, the length of the stamens. Berried drupes five, obovate, kidney-form, distant, erect, at first red, afterwards brown, somewhat wrinkled: pulp thin, drying to a coriaceous crust: shell the form of a drupe, somewhat bony, one-celled, valveless. Seeds solitary, kidney-form, softish to the touch[b].

This tree is only about twelve feet high, with a slender trunk; the bark is brownish red, the wood whitish, with a greenish heart. The flowers are yellow, and have no scent[c]. Native of the East-Indies.

2. Branches alternate, flexuose at top, covered with a brown bark, round, smooth, as is the whole plant. Leaves on very short petioles, alternate, from two to three inches long, two inches broad, coriaceous, scarcely veined, very smooth and even, with mucronate serratures, but quite entire at the base. Panicle strict, spreading, a hand or more in length; partial peduncles and pedicels alternate; squarrose with the permanent pedicels after the flowers have fallen off. Flowers before their evolution ovate, obtuse. Calycine leaflets the length of the petals, lanceolate. Petals yellow. Filaments ten small tubercles. Anthers the length of the corolla, awl-shaped. Germ five-cornered. Style the length of the anthers. Stigma acute[d]. Native of the West-Indies.

3. This also is very smooth. The branches are alternate, and covered with an ash-coloured bark. Leaves petioled, scattered, sharp at the base, very blunt at the top, two inches long, shining, veinless, subcoriaceous. Petiole very short, thickened at the insertion. Panicle like that of *Ochna squarrosa*; peduncles spreading very much, many of them a little bent in, purple. Calycine leaflets lanceolate. Corolla the length of the calyx. Berries placed on a receptacle.

Native of the East-Indies[e].]

DESCRIPTIONS, *&c.*

1. This is an annual plant, rising with an upright branching stalk, about two feet high. Leaves opposite, [sessile, quite entire, hispid.] Branches and peduncles also opposite; the latter axillary, long and naked, except that there are two short leaves close under each head of flowers. These heads at their first appearance are globular, but as they increase

crease in size become oval. [Calyx five-leaved, white-tomentose, involucred with three scales, two of which are very large, boat-shaped, keeled, coloured, converging. Corolla none, unless the tube of the stamens be reckoned as such. Filaments united into a conical tube, quite entire, except that it is five-toothed at top. Germ superior. Style single, bifid. Capsule roundish, compressed a little, membranaceous, semipellucid, one-celled, cut round above the middle, the upper valve shorter. Seed smooth, fulvous, inverted[a].

Native of India. It was cultivated in 1714 by the Dutchess of Beaufort[b]; but was not common in the English gardens till 1725. It was raised first in Holland about 1670[c].] Mr. Miller says that he received seeds of the white sort from Holland in 1722. The flowering heads are beautiful, and if gathered before they are too far advanced, will retain their beauty several years. The seed ripens late in autumn, and the plant decays soon after.

There are two varieties, one with fine bright purple heads, the other has white or silvery heads, and these never alter from seeds, so that they are permanent varieties, though in other respects they do not differ: there is also one with mixed colours, but whether this arose accidentally from the seeds of either of the former, I cannot determine, for this variety continues from seeds, and the other two I have cultivated more than thirty years, and have never found either of them vary.

There are also two varieties of this which grow naturally in the West-Indies, one with purple, and the other with white heads, which are much smaller and rounder than those before-mentioned. The plants grow much larger, and spread more into branches, and they are later before they flower, so that in cold seasons the seeds rarely ripen in England; these are called Bachelors Buttons by the inhabitants of America.

[Loureiro also mentions a variety in Cochinchina, with white ovate heads, in which all the florets are fertile; whereas in the purple variety most of them are barren.]

2. Stems upright, hairy, slender. Leaves opposite, hairy, sessile. Heads of flowers terminating, small, spreading so that the calyxes appear distinct; they are of a pale straw-colour, and appear in July.

[It was cultivated in the Eltham garden before 1732, and was there raised from seeds brought from Buenos Ayres by Mr. Mylam[d].

3. Height a cubit and half. Stems quadrangular, jointed, woody, with longish white hairs on them, and having a pair of decussated branches at each joint. Leaves opposite at each joint, small, oblong and narrow, thin, soft, having a few hairs on them. Heads of flowers rounded-oblong, at first white, but becoming blue. Native of Malabar[e].

4. This is somewhat higher than the first sort; the heads are white, smaller, and composed of smaller calyxes, without any leaves at the base. Native of Brasil[f].]

5. Stems more slender and tall than those of the first, and growing irregularly. Leaves smaller, but of the same shape. Flowers in spikes at the ends of the branches, broken or divided into three or four parts, small, and of a pale purple colour. The seeds were sent by Dr. Houston from Campeachy: [and it was cultivated by Mr. Miller before 1733.

6. Root annual. Stem shrubby at bottom, from one to two feet high. Branches jointed, subdecumbent, lanuginose, white. Leaves at the root aggregate, sessile; above opposite, lanceolate, obtuse, tomentose, beneath white-lanuginose, soft. Flowering-stems leafless, stiff, whitish, except that they are often purple towards the end. Flowers in spikes, aggregate, sessile, interrupted, lanuginose. Scales two or three, membranaceous, minute, forming an involucre to the calyx, which is five-parted; the parts linear, erect, purple, woolly on the outside. Germ large, compressed, woolly: style short; stigma subcapitate, yellow. Capsule largish, involved in the calyx, opening in two parts at top, woolly, compressed, crested at the edge. Native of dry sandy fields in the southern parts of Jamaica[g]; and other parts of the West-Indies. Introduced into the Paris gardens by seeds sent from St. Domingo in 1778 by Jac. Rob. Crosnier[h]; and into the Kew garden in 1784 by Monf. Thouin[i]. See *Celosia procumbens*.

7. At each joint of the stem two opposite pedonecles are produced, longer than the leaves, trifid at top, with one globular head of flowers at the end of each division, having no leaves immediately under them. Native of La Vera Cruz[k], where it was found by Houstoun.

8. Stem round, simple, hairy. Leaves opposite, on short petioles, oval, obtuse, leathery, quite entire, having hairs scattered over them. Several bractes under each flower, sharper than the leaves, and of the same length with the flower. Flowers aggregate, terminating the size of a walnut. The florets sessile, very numerous. Calyx five-leaved: leaflets subulate, flat, woolly at bottom, an inch in length. Corollet cylindric, the length of the calyx. Germ superior, minute.—This is very different from its congeners; it is, however, a genuine species of this genus.—Found in New Granada, by Mutis[l].

9. Stem herbaceous, erect, four-cornered, with short hairs pressed close: branches opposite, quite simple, higher than the stem, subuliform, two-leaved. Leaves sessile, narrow, attenuated, an inch and half long, with minute hairs pressed close, and visible only with a glass, pale green, quite entire. Peduncles terminating the branches, elongated. Heads first oblong, then cylindrical, obtuse; at the base of each, leaves usually three, very seldom two, of the same structure with the stem-leaves, longer than the heads. Calycine leaflets ovate, concave, mucronate; the keel subciliate. Petals five, lanceolate, concave, pubescent on the outside, and almost equal. Filaments connected at the base by means of a membrane. Germ oblong, smooth. Style single. Stigma simple.—It has the habit of Gomphrena, but differs in having a single style.—Native of the East-Indies, where it was found by Koenig[m].]

PROPAGATION AND CULTURE.

The first sort is a very ornamental plant in gardens, and is now very commonly cultivated in the English gardens. In Portugal, and other warm countries, it is cultivated to adorn their churches in the winter; for if the flowers are gathered when they are fully grown, and dried in the shade, they will retain their beauty a long time, especially if they are not exposed to the air; this plant is annual, and therefore is only propagated by seeds, which should be sown on a good hot-bed the beginning of march; but if the seeds are not taken out of their chaffy covering, it will be proper to soak them in water for twelve hours before they are sown, which will greatly facilitate their growing. When the plants are come up half an inch high, they should be transplanted on a fresh hot-bed, at about four inches distance, observing to shade them till they have taken root; then they should have fresh air admitted to them every day, in proportion to the warmth of the season; they will also require to be frequently refreshed with water. In about a month's time, if the hot-bed is of a proper warmth, the plants will have grown so large as nearly to meet, therefore they will require more room, otherwise they will draw up weak; then a fresh hot-bed should be prepared, into which there should be a sufficient number of three *farthing* pots plunged, filled with light rich earth, and when the bed is in a proper temperature of warmth, the plants should be carefully taken up with balls of earth to their roots, and

each

each planted into a ſeparate pot, obſerving to ſhade them till they have taken new root, afterward they muſt be treated in the ſame manner as other tender exotic plants. When the plants have filled theſe pots with their roots, they ſhould be ſhaken out of the pots, and their roots on the outſide of the ball of earth muſt be carefully pared off; then they ſhould be put into pots a ſize larger, and when there is conveniency of a deep frame, to plunge the pots into another gentle hot-bed, it will bring the plants early to flower, and cauſe them to grow much larger than thoſe which are placed abroad. In july the plants ſhould be inured gradually to bear the open air, into which they may be removed about the middle of that month, and intermixed with other annual plants to adorn the pleaſure-garden; but it will be proper to keep a plant or two of each ſort in ſhelter for ſeeds, becauſe when the autumn proves cold or wet, thoſe plants which are expoſed abroad, ſeldom produce good ſeeds.

§ The plants of this ſort will live two or three years in a ſtove; and the ſeeds will ſometimes ripen in England.

Lin. ſyſt. 164. *Thunb. diſſ.* 3. 55. *fl. jap.* 69. *t.* 15.

DESCRIPTION, *&c.*

Root fibrous, annual. Stem one or more, four-cornered, decumbent at the baſe, branched at top, ſcarcely a ſpan in height. Leaves oppoſite, on very ſhort petioles, ovate, acute, ſerrate, ſmooth, ſpreading, a line in length. Flowers on the branches in ſpikes, remote, moſtly on one ſide, drooping, minute. Found by Thunberg abundantly about Nagaſaki, flowering in auguſt*.

GOODENIA. (*So named by Dr. Smith, preſident of the Linnean Society, from the Right Rev. and learned Samuel Goodenough, L. L. D. F. R. S. Biſhop of Carliſle, author of obſervations on the Britiſh ſpecies of Carex, &c.*)

Lin. tranſ. 2. 346. *Smith hot. nov. hall.* 15. *t.* 5.

Claſſ. 5. 1. Pentandria Monogynia.

Nat. order of *Campanulaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-leafed: *leaflets* equal, awl-ſhaped, erect, permanent.

COR. one-petalled, ſuperior: *tube* cloven on the upper ſide from top to bottom: *limb* five-cleft; ſegments equal, obovate, directed forwards.

STAM. *Filaments* five, ſhorter than the tube, and projecting through its ſiſſure. *Anthers* linear, vertical, two-celled.

PIST. *Germ* inferior, five-angled. *Style* ſimple, longer than the ſtamens, and ſtanding out with them. *Stigma* cup-ſhaped, ciliated.

PER. *Capſule* two-celled, two-valved; burſting at top, and becoming revolute; the partition, which is parallel to them, remaining erect.

SEEDS ſeveral in each cell, imbricated, lenticular.

ESSENTIAL CHARACTER.

Cor. longitudinally cloven on the upper ſide, expoſing the organs of fructification; border five-cleft, leaning one way. *Anthers* linear. *Stigma* cup-ſhaped, ciliated. *Capſ.* two-celled, two-valved, with a parallel partition. *Seeds* many, imbricated.

SPECIES.

1. Goodenia ovata. *Ovate yellow Goodenia.*
Smith in Linn. tranſ. 2. 347.
Leaves ovate, toothletted-ſerrate, both they and the corollas ſmooth, fruit linear.
2. Goodenia albida. *White-flowered Goodenia.*
Smith in Linn. tranſ. 2. 348.
Leaves obovate, toothed, both they and the corollas ſmooth, ſtyle and ſtem hairy.
3. Goodenia paniculata. *Panicled yellow Goodenia.*
Smith in Linn. tranſ. 2. 348.
Leaves obovate-lanceolate, toothed, both they and the corollas hairy, ſtem almoſt naked, panicled.
4. Goodenia bellidifolia. *Daiſy-leaved yellow Goodenia.*
Smith in Linn. tranſ. 2. 349.
Leaves obovate, toothletted, fleſhy, ſtem almoſt naked, ſpiked, corolla hirſute on the outſide, fruit four-valved.
5. Goodenia ſtricta. *Rigid blue Goodenia.*
Smith in Linn. tranſ. 2. 349.
Leaves lanceolate, entire or toothed, fleſhy, ſmooth, corolla hirſute on the outſide, ſtigma contracted at the mouth.
6. Goodenia ramoſiſſima. *Branching blue Goodenia.*
Smith in Linn. tranſ. 2. 349. *bot. nov. holl.* 15. *t.* 5.
Leaves linear-lanceolate, ſomewhat toothed, both they and the ſtem hiſpid, ſtyle very hirſute at top, corolla hairy on the outſide.
7. Goodenia heterophylla. *Various-leaved Goodenia.*
Smith in Linn. tranſ. 2. 349.
Leaves entire, toothed or lobed, hairy, fruit roundiſh, corolla almoſt naked.
8. Goodenia hederacea. *Trailing Goodenia.*
Smith in Linn. tranſ. 2. 349.
Leaves roundiſh, entire or five-lobed, corolla woolly on the outſide, ſtem proſtrate.
9. Goodenia lævigata.
Curt. magaz. 287.
Leaves ovate-lanceolate, toothed, ſmooth.

DESCRIPTIONS, *&c.*

This genus ſhould be inſerted between *Scævola* and *Cinchona* in the Linnean ſyſtem, and between *Cyphia* and *Scævola* in that of Monſ. de Juſſieu. It differs eſſentially from *Scævola* in its fruit; from *Cyphia* in its corolla, and from *Lobelia* in its ſtamens.

Dr. Smith has given this new and moſt diſtinct genus the name of Goodenia, in honour of his worthy friend Dr. Goodenough. In the conſtruction of this name he has followed the example of Tournefort, in forming *Gundelia* from Gundelſcheimer. Dr. Goodenough's name might however have been ſoftened into *Goodenovia*, without being either too long, or offending a delicate ear.

Theſe plants are all natives of New South Wales, about Port Jackſon.

1. Stem ſhrubby, erect, angular, branched, leafy. Leaves alternate, varying a little in breadth, acute, ſerrated with fine ſharp ſpreading unequal teeth, of a bright green, veiny, ſmooth on both ſides, paler beneath: footſtalks channelled above, with a tuft of down on their axils. Stipules none. Flowers yellow, from three to five in a dichotomous panicle, ariſing ſolitary from each axil of the uppermoſt leaves, and above half as long as the correſponding leaf: peduncles ſomewhat angular, ſmooth, with two awl-ſhaped bractes at each ſubdiviſion. Calycine leaflets ſmooth. Corolla tubular: tube ſmooth, greeniſh and ſtriated externally; limb yellow, membranous, with a thick greeniſh plait running from the tube to the point of each ſegment behind. Filaments inſerted into the receptacle, equal, perfectly diſtinct. Germ long, ſlender, ſmooth: ſtyle ſmooth: ſtigma large, bent down towards the ſtamens, finely ciliated. Capſule oblong, crowned with the calyx. Seeds roughiſh, encircled with a groove.

* Thunb. jap. & gen.

This plant is in the garden of the Duke of Northumberland at Sion, and was presented in flower on the 4th of december, 1792, to the Linnean Society by Mr. Thomas Hoy, one of the fellows.

2. Gathered by John White, Esq. Surgeon at Port Jackson.

3. Gathered at the same place by Mr. David Burton.

4. Found at the same place by John White, Esq.

5. This grows naturally in marshy ground at Port Jackson, flowering there in october, and was found by the same gentleman[a].

6. Stem herbaceous, two or three feet high, much branched and straggling, round rough with short stiff hairs, as are also the leaves. The latter are of a narrow lanceolate form, mostly entire, but sometimes toothed, and even sinuated. Stipules none. Flowers solitary, terminating the branches, and appearing in october. The plaits of the corolla are externally hairy. The anthers are very minutely bearded. The style is very hairy in its upper part. The germ is oval and hairy[b]. Found by John White, Esq. at Port Jackson.

7, 8. Natives of the same place, and found by the same gentleman. We do not yet know the colour of their flowers[c].

9. Stems round, smooth, green below, purplish above. Leaves alternate, on footstalks gradually widening into them, somewhat ovate, deeply toothed, of a full bright green. Flowers axillary, forming a thin spike, sessile, pale violet, having a peculiar, rather unpleasant smell; at the side of each flower two long narrow bractes. Calycine leaflets short, ovate, appearing edged with hairs when magnified. The lower part of the corolla, which at first is tubular, splits longitudinally above, and forms a kind of half tube, the edges of which are brown, the inside yellow, the outside greenish, the mouth beset with short hairs, each of which is terminated by a small villose head: the segments of the limb or border are linear, spread out like a hand, and are terminated by short points. Filaments whitish, somewhat broader above, rather flat, inserted into the receptacle. Anthers oval, flattened, yellow, a little bent, and the length of the pistil when the flowers are not yet fully expanded; afterwards they are much shorter than the pistil, and appear withered. The style, in flowers about to open, is about the length of the filaments, and upright; afterwards it is much longer, and bent somewhat downward. Stigma at first upright, in form of a cup, having the edge curiously fringed with white hairs; afterwards it closes together, loses its hollow, assumes a flat appearance, and nods a little; the back part of it is bearded. Germ oblong, usually abortive with us.

Raised by Mr. Curtis in the summer of 1793 from seeds brought over in specimens of earths from Botany-Bay by Captain Tench to Samuel Tolfrey, Esq. It flowers from july to october[d].

PROPAGATION AND CULTURE.

These plants must be raised from seeds brought from their native country. When once obtained, they may readily be increased from cuttings. They are not very tender, but may be preserved in the dry stove, or a good glass case.

3. Gordonia Franklini.
L'Herit. ß. nov. 156.
Franklinia Alatamaha. *Marsh. arbust.* 49. *Bartr. trav.* 16 & 467.
Leaves smooth, flowers sessile, fruits globular.

DESCRIPTIONS, &c.

Shrubs, with flowers solitary from the axils. In habit they differ somewhat from the Malvaceous tribe, and they have no stipules, but the corole or heart of the seed is furnished with corrugated lobes[e]. The filaments not being united at bottom, but only inserted into the nectary, these shrubs do not properly belong to the class Monadelphia, but to that of Polyandria.

1. Catesby describes the Loblolly Bay as a tall and very straight tree, with a regular pyramidal head, and adds that the leaves are shaped like those of the common Bay, but are serrated. Swartz says it is a low tree, with a white, soft, brittle wood; the leaves ovate-lanceolate, flat, somewhat leathery, of a dusky green colour. According to Mr. Miller, the stem is five or six feet high, and branched; the leaves four inches long, and one inch and a half broad in the middle, slightly indented on their edges, and of a thick consistence; the flowers axillary, on very long peduncles; the petals are yellow and thick; the stamens are joined at their base to the style, and form a short column, but spread open at top, filling the mouth of the tube[f].

Calyx tomentose, villose at the edge. Stamens scarcely longer than the calyx[g].

Native of North America. Introduced about 1768, by Benjamin Bewick, Esq. It flowers in august and september[h].

Dr. Dale sent seeds of it to Mr. Miller from South Carolina, and he raised plants from them.

2. Branches subpubescent. Leaves as in the foregoing, but with the lower surface very softly tomentose. Flowers axillary, solitary, sessile towards

[a] Smith in Linn. transf. [b] Smith in bot. New. Holl. [c] Smith in Linn. transf. [d] Curtis.

[e] Jussieu. [f] Dict. edit. 7. [g] Linn. spec. [h] Hort. kew.

the tops of the branches. Leaflets of the outer calyx subovate, acuminate at the tip, tomentose, as are also those of the inner[1].

Native of South Carolina. Introduced in 1774, by Mr. William Malcolm. It flowers in september[2].

It has been long in the open air in the garden at Trianon in France; but, like the rest of the trees and shrubs from South Carolina, not very patient of cold. The flowers are white, but they come out so late, that the frosts destroys them before they expand[3].

3. This beautiful tree-like shrub rises with an erect trunk to the height of about twenty feet, with alternate branches. Leaves oblong, narrowed towards the base, serrate, alternate, sessile or subsessile. Flowers towards the extremity of the branches, solitary, sitting close in the bosom of the leaves, often five inches in diameter when fully expanded; petals snow-white, the lower one hollow, formed like a cap or helmet, entirely including the other four, until the moment of expansion; its exterior surface is covered with short silky hairs; the borders of the petals are curled or plaited. Fruit a large, round, dry, woody pericarp, opening at each end oppositely by five alternate fissures, containing ten cells, each filled with dry woody cuneiform seeds[4]. Capsules umbilicate, with the partitions in the middle of the valves. Seeds very many, lying over each other in two rows, in each cell, obscurely cornered, somewhat like those of the Cypress, slightly edged at the corners.

Native of the South Carolina and Georgia. Not having yet flowered in Europe, it is doubtful whether this species belongs to the genus Gordonia or Stuartia. As far as can be judged from specimens, it rather appertains to the latter. It has the habit and calyx of the former, but the insertion of the stamens, and manner of flowering, are the same as in Stuartia; the capsule also agrees rather with the latter, but the seeds are in two rows, edged however at the corners, not winged as in Gordonia[5].

The flowers have the fragrance of a China Orange. It was first observed by Mr. John Bartram on the Alatamaha river in Georgia, in the year 1760; and was brought into Pennsylvania fifteen years after, by his son William Bartram[6].]

PROPAGATION AND CULTURE.

The Loblolly Bay growing naturally in water, is not kept alive in this country without difficulty. Mr. Miller raised several plants, which continued till winter, but not one of them survived, though he placed some of them in the stove, and supplied them well with water.

GORTERIA. (*So named in honour of David de Gorter, author of* Flora Zurphanica & Ingrica.)

Lin. gen. n. 982. *Reich.* 1064. *Schreb.* 1328. *Juss.* 182. *Gærtn. t.* 171.

Class. 19 3. Syngenesia Polygamia Frustranea.

Nat. order of *Compositæ Capitatæ.—Corymbiferæ*, Juss.

GENERIC CHARACTER.

CAL. *Common* one-leafed, imbricate with spiny scales, the inner ones gradually longer, straight, bristle-shaped, rigid.

COR. *Compound* radiate. *Corollets* hermaphrodite, several in the disc—female fewer in the ray.—*Proper* of the hermaphodite funnel-form, five-cleft—of the female ligulate, lanceolate.

STAM. in the hermaphrodites, *filaments* five, short. *Anther* cylindric, tubular.

PIST. of the hermaphrodites, *germ* obsolete; *style* filiform, the length of the corollet; *stigma* bifid.—of the females, *germ* obsolete; *style* none; *stigma* none.

PER. *Calyx* unchanged, reclinated.

SEED. in the hermaphrodites, solitary roundish; *down* simple (woolly, *Juss.*)—in the females, none.

REC. naked. (Not so in all the species: see n. 1, 3.)

9. Gorteria hispida. *Hairy Gorteria.*

Lin. syst. 784. *suppl.* 381.

Leaves oblong, ciliate-spinous, upright, smooth, calyxes entire, ending in a thorn.

10. Gorteria spinosa. *Thorny Gorteria.*

Lin. syst. 784. *suppl.* 381.

Rohria obovata. *Vahl in act. Hafn.* 3. 1. *p.* 106.

Leaves oblong, sessile, tooth-spinous, spreading, smooth, calyxes ciliate-spinous, flowers upright.

11. Gorteria cernua. *Drooping Gorteria.*

Lin. syst. 784. *suppl.* 382.

Leaves oblong, clasping, tooth-spinous, spreading, smooth, calyxes ciliate-serrate, flowers drooping.

12. Gorteria unillora. *One-flowered Gorteria.*

Lin. syst. 784. *suppl.* 382.

Leaves lanceolate, undivided, tomentose underneath, stems one-flowered, depressed.

13. Gorteria barbata. *Bearded Gorteria.*

Lin. syst. 784. *suppl.* 382.

G. fruticosa. *Berg. cap.* 302.

Leaves elliptic-lanceolate, tooth-awned, calyxes pedunculed, ciliate-setaceous.

DESCRIPTIONS, &c.

These are mostly shrubby plants from the Cape of Good Hope. The first and third are herbaceous and annual.—The flowers are terminating. Jussieu thinks it probable that on farther examination it will be found that several species are placed in this genus that do not belong to it. He doubts whether G. *rigens* is not more nearly related to the genus *Arnica*.

—Gærtner

—Gærtner alſo is of opinion, that the Linnean genus comprehends ſeveral plants that are foreign to it.

1. Stems a ſpan high, little branched, roundiſh, hairy. Leaves alternate, narrow-lanceolate, ſeſſile, hiſpid, white-tomentoſe underneath; the larger ones uſually cut with two deep gaſhes on each ſide. Calyxes terminating, ovate; ſcales mucronate, the points ſtraight, ſtiff, but hardly to be called prickly. Ray yellow, at the baſe and underneath blue [a].—Receptacle briſtly, rough in the middle, excavated in the circumference. Florets in the centre male; in the diſk androgynous, and of theſe not more than five fertile; in the ray female or neuter, and barren. Seeds woolly, but without down or feather.—When the flower comes to maturity, the aperture of the calyx being very narrow, the ſeeds do not fall out, but the whole drops together. Hence, when one of them germinates, the radicle not only perforates the bottom of the calyx, but is ſo firmly united to it, that the young plant bears the maternal calyx permanent above the root. There is no other inſtance of this economy, except in Neurada [b].

Introduced 1774, by Mr. Francis Maſſon. It flowers in july and auguſt [c].

2. This a low ſpreading plant, with woody ſtalks ſix or eight inches long trailing on the ground, having two or three ſide branches, each terminating in a cloſe head of leaves, which are narrow, green on their upper, but ſilvery on their under ſurface, and cut into three or five ſegments at the end. The peduncles ariſe from theſe heads, are ſix inches long, naked, and ſupport one large orange-coloured flower: each floret in the ray has a dark mark towards the baſe, with white intermixed. It flowers in may and june.

[The green-houſe can ſcarcely boaſt a more ſhewy plant. The flowers, when expanded by the heat of the ſun, and it is only when the ſun ſhines on them that they are fully expanded, exhibit an unrivalled brilliancy of appearance [d]. Mr. Miller cultivated it in 1755 [e]. He received it from Adrian van Royen, profeſſor of Botany at Leyden, and diſtributed it to many curious perſons in England [f].

3. Stems a foot high, angular, red, commonly ſmooth, but ſometimes lanuginous here and there. Leaves ſcattered, ſeſſile, claſping, ſubdecurrent, ſmooth, but here and there lanuginous. Flowers terminating, ſolitary: outer ſcales of the calyx, ſhort, palmate-ſpinous; inner longer, lanceolate, ending in a thorn, and armed with ſpinules at the baſe on each ſide. Corollets of the ray wholly barren, the petal four-cleft at the end, an inch long, ſpreading, yellow, but near the tip underneath of a dirty purple colour. Corollets of the diſk yellow. Seeds obovate. Receptacle chaffy; chaffs long, ſlightly connate, net-wiſe. Native of the Cape of Good Hope. Mr. Fr. Maſſon. Introduced 1774. It flowers in july [g].

4. Stem proliferous, villoſe. Branches from the baſe of the ſtalk. Leaves as it were glued together at the baſe, bowed back, imbricate downwards, ending in a thorn, ciliated with three or four ſpinules on each ſide. Calyx terminating, ſquarroſe, with leaflets bowed back, like thoſe on the ſtem. Ray of the flowers yellow [h].

Introduced in 1786, by Baron Hake. It flowers from june to auguſt [i].

5. Stem five feet high, upright, very much branched. Branches alternate. Leaves glued together at the baſe, bowed back, diſtant, with three briſtle-ſhaped ſpines on each ſide, and one at the end. Flowers yellow, the ray violet-coloured underneath.—It differs from the foregoing, in the ſtem being neither villoſe nor proliferous; the leaves not imbricate downwards, but broader, ſhorter, with yellow briſtles ſtanding out on the edge; the flowers peduncled, not ſeſſile, and finally in the colour of the ray beneath [k].—Native of the Cape and of China.

6. The leaves are imbricate, and preſſed to the ſtalks, ſo as to cover them in an extraordinary manner [l].

Introduced in 1774, by Maſſon. It flowers in may and june. [m]

7. Stem ſlender, three feet high, ſending out a few weak branches, [which are tomentoſe and white. Leaves like thoſe of Privet, alternate, ſharp, petioled, having ſix or ſeven ſerratures briſtly at the end. Flowers terminating, ſubſolitary, peduncled, the peduncle longer than the flower. Calyx many-leaved, in two rows; the inner a little ſmaller: ſeaſlets lanceolate, having a thorn at the end, not ſerrate; ciliate, with five or ſix ſtiffiſh briſtles on each ſide, much ſhorter than the leaflet. Corolla yellow, radiate: the ray has many flowers, and is twice the length of the calyx; the diſk is convex the ſegments of the florets linear. Seeds villoſe. Crown of the ſeeds ſtar-form, with many leaflets [n].—Cultivated in 1739, by Mr. Miller. It flowers in auguſt and ſeptember.—This is entirely different from the *G. fruticoſa* of Bergius (cap. 302.), which is *Atractylis* oppoſitifolia. *Lin. ſyſt.* [o].

8. Stem ſcarcely a foot high, herbaceous, ſmooth, very little branched. Root-leaves broad-lanceolate; petioled, quite entire, bluniſh; ſtem-leaves alternate, cordate, acute, the upper ones gradually ſhorter. Flowers terminating, ſeſſile. Calyx like that of an Artichoke, but ſcarcely bigger than a plum, imbricate, ſmooth at the edge, thorny at the end, ſtraight.

9. Shrubby and large.

10. Both thoſe were found at the Cape by Thunberg.

11. The baſe of the calyx is ſingular, with ripe ſeeds, and reſembles the fruit of Medicago [p].—Introduced 1785, by Baron Hake. It flowers in may [q].

12. Stems a ſpan high, ſimple, herbaceous, leafy on all ſides. Leaves alternate, ſeſſile. Peduncle terminating, longer than the leaves. Ray of the flower yellow. It has the appearance of *G. rigens*, and may perhaps be a variety of it.

13. Stems diffuſed, ſimple, white-tomentoſe. Leaves oppoſite or alternate, ſeſſile, acute, ſmooth, marked with lines, awned at the end on both ſides with four or five lateral teeth, white-tomentoſe underneath. Peduncle terminating, very long, leafleſs, putting off a white nap, one flowered. The outer order of leaflets in the calyx is of the ſame form with the leaves; the inner is coloured, more copious, narrower, and ends in abundance of briſtles that are twice as long as the flower [r].]

PROPAGATION AND CULTURE.

Moſt of theſe plants may be increaſed by cuttings, planted in a ſhady border, during any of the ſummer months; afterwards they may be treated like other plants from the Cape. For this ſee *Arctotis*. [The two annual ſorts muſt be propagated by ſeeds.]

7. The ſeventh ſort is increaſed by planting the ſmall heads at the end of the branches, in june and july: theſe muſt be cloſely covered with either bell or hand-glaſſes, and carefully ſcreened from the ſun. When they are well rooted, they ſhould be put each into a ſmall pot, and in winter placed in an airy glaſs caſe ſecure from damp.—[This may ſerve as a direction for any other ſorts, and indeed for moſt ſhrubby plants, that will not take from cuttings in the ordinary way.

GOSSYPIUM. (*Vossius is of opinion that this is an Egyptian word, it is called ξυλον in Greek. See Plin. l. 19. c. 1.*)

Engl. *Cotton.* Fr. *Coton.*

Lin. gen. n. 845. *Reich.* 910. *Schreb.* 1138. *Cavanill. diff.* 6. 309. *Juss.* 274. *Gærtn. t.* 134.

Xylon. *Tournef.* 27.

Class. 16. 6. Monadelphia Polyandria.

Nat. order of *Columniferæ*. *Malvaceæ* Juss.

GENERIC CHARACTER.

CAL. *Perianth* double: *outer* one-leafed, trifid, flat, larger; *inner* one-leafed, bluntly emarginate in five rows, cup-form.

COR. *Petals* five, obcordate, flat, ſpreading, faſtened by their baſe to the tube of the ſtamens.

STAM. *Filaments* numerous, uniting at bottom into a tube, ſeparate at and below the tip, lax, inſerted into the corolla. *Anthers* kidney-form.

PIST. *Germ* roundiſh. *Style* columnar, the length of the ſtamens. *Stigmas* three or four, thickiſh.

PER. *Capſule* roundiſh, acuminate, three or four-celled: *partitions* contrary.

SEEDS very many, oval, involved in cotton.

ESSENTIAL CHARACTER.

Cal. double; outer trifid. *Caps.* four-celled. *Seeds* wrapped in cotton.

   Lin. ſpec. 975. *Reich.* 3. 357. *hort. upſ.* 204. *Swartz obſ.* 266. *Pluk. alm. t.* 188. *f.* 1.
   Leaves three-lobed quite entire with three glands underneath.

DESCRIPTIONS, &c.

[1. *Root* tapering, woody with numerous fibres, annual. *Seed-lobes* two, kidney-form, terminating gradually in a long petiole with the figure of a halved funnel. *Stem* three feet high, upright, round, pubeſcent, as is the whole of the herb, at bottom brown with ſtraight chinks, at top ſpotted with black: *branches* axillary, ſcarcely longer than the leaf at their origin. *Leaves* alternate, only half the length of the petiole, tomentoſe, odorous whilſt young. *Petioles* round, tomentoſe, bent in towards the inſertion of the leaf, at the baſe gibbous and thicker, ſpreading. *Stipules* two, lanceolate, at the baſe of the petioles and peduncles. *Peduncles* ſhorter than the petioles, branched. *Calyx* outer, when cloſed, three-cornered: when open, three-parted almoſt to the baſe; ſegments heart-ſhaped, gaſhed, ſhorter by half than the corolla, dotted with black: inner cylindrical, only one-third of the others length, upright, five-parted, with ſhort blunt ſegments dotted like the inner. *Corolla* monopetalous, with a very ſhort tube, and a five-parted, ſpreading border, the ſegments blunt, crenate at the ſide, pale yellow with five red ſpots at bottom, and deciduous. *Filament* coaleſcing into a pyramid. *Germ* ſuperior ovate: *ſtyle* filiform: *ſtigma* fourfold. *Capſule* bluntly three-cornered, three-valved, three-celled. *Seeds* ovate, about three in each cell, convex on one ſide, more flat on the other, immerſed in fine cotton[a].]

This is the common Levant Cotton, which is cultivated alſo in ſeveral iſlands of the Archipelago; and in Malta, Sicily, and the kingdom of Naples, as well as in moſt parts of Aſia.

[It is a native of the Eaſt Indies: and was cultivated here by Gerarde, as a garden plant, in 1594[b]. "It groweth (ſays he) about Tripolis and Alepo in Syria, from whence the factor of a worſhipfull merchant in London, Maſter Nicholas Lete, did ſend unto his ſaid maſter divers pounds weight of the ſeed, whereof ſome were committed to the earth at the impreſſion hereof (1597): the ſucceſs we leave to the Lord. Notwithſtanding myſelf three years paſt did ſow of the ſeeds, which did grow very frankly, but periſhed before it came to perfection, by reaſon of the cold froſts that overtook it in the time of flowering."

Few plants are more uſeful, ſince it furniſhes materials for clothing in the four quarters of the world, particularly to the Aſiatics. The ſeeds alſo are an article of food, and eſteemed wholeſome.

2. Stem eight feet high, the thickneſs of the human leg, with a rugged brown bark, and long diffuſed, twiſted branches. Leaves three or five-lobed, without glands, ſmooth, ſcattered, petioled: the lobes ſhort. Flowers entirely yellow, terminating, ſolitary. Outer calyx three-leaved, large, gaſhed, erect: the inner calyx five-notched. Capſule commonly three-cornered, three-valved, three-celled, ſubovate, acuminate, rugged[c].—Between the ſinuſes of the leaves there is frequently a ſmall ſegment; hence all the ſinuſes are obtuſe[d].

Native of the Eaſt Indies, and the eaſtern coaſt of Africa. Cultivated in 1731, by Mr. Miller[e].

3. Stem ſhrubby, a fathom in height, erect, ſtriated. Branches hirſute. Leaves alternate; the upper ones undivided, cordate, acute, entire, rough with hairs about the edge; the lower three lobed, the lobes little divided, ovate, acute, entire, hirſute beneath, ſmooth above. Petioles round, ſtriated, dotted with black, hirſute. There is a ſingle glandular pore on the midrib underneath, and ſometimes two or three on the next nerves. Peduncles three times ſhorter than the petioles, thick, ſtiff, hirſute, dotted with black. Outer calyx three or five-cleft, the ſegments ovate, acute, rough with hairs; the inner truncate, with three blunt teeth. Petals rounded, retuſe, entire, yellow at the baſe, purple at the tip, pubeſcent on the outſide. Germ ovate, acuminate, dotted with black: ſtyle longer than the ſtamens, three or five-cleft at top, inclined. Capſule large, ovate, dotted with black, three-celled, three-valved. Seeds ovate, acute, green[f].

This is planted, ſays Browne, in a few gardens in Jamaica, but is not much cultivated, for the Cotton is not thought to be ſo good, and the ſeeds are ſo ſmall, that it is a difficult matter to ſeparate them from the Cotton. It grows however more luxuriant than the common, and riſes generally from ſeven to nine feet in height, bearing a great number of ſeed-veſſels on all the branches.

Swartz mentions a variety, called *Cotonier de Soie* (Xylon americanum præſtantiſſimum, ſem. viref-

[a] Murr. prodr. [b] Hort. kew. from Ger. herb. [c] Loureiro. [d] Linn. fyſt. [e] Hort. kew. [f] Swartz.

centi-

centi. *Tournef.*) the Cotton of which is better than any of the reſt.

4. This is a ſhrub, with branches ſcarcely hairy, but having ſmall black dots ſcattered over them, as the petioles alſo have. Leaves cordate, deeply three-lobed, in a very fertile ſoil five-lobed, as big as the palm of the hand, acuminate, with a ſingle gland under the midrib. The ſtamens are entirely monadelphous[a].

According to Swartz, the ſtem is a fathom in height, biennial, roundiſh, rugged: branches ſpreading very much, angular, ſtriated. Upper leaves three-lobed, lower five-lobed; lobes ovate, entire, nerved, pubeſcent; with three glandular pores underneath on the midribs of the leaves. Petioles long, round, patulous, hirſute, with black atoms ſcattered over them. Flowers oppoſite to the petioles, large, ſulvous; on ſhort, dotted peduncles. Outer calyx ſubtriphyllous, pubeſcent, dotted[b]: the ſegments large, deeply and unequally toothed; the inner is very ſhort, and five-lobed in waves. Capſule leathery, thickiſh, three-celled, three-valved; the partitions inſerted in the middle of the valves, which are wrinkled within, and the edges turn back after they open. There is no receptacle, but the ſeeds are fixed in a double row to the central angle of the cells. Seeds about ſix in each cell, ovate, tapering towards the umbilicus, convex on one ſide, angular on the other, and white[c].

Native of India, China, and the Society Iſles. Cultivated in Jamaica. Introduced here in 1777, by Daniel Charles Solander, L. L. D. It flowers in july[d].

5. Stem four or five feet high, perpendicular, round, ſtraighter at the baſe, the thickneſs of a ſwan's quill, above flexuoſe and thicker, ſomewhat angular, ſwelling at the origin of the branches, green, rugged, pubeſcent, branched. Leaves large, horizontal or oblique, cordate, broad; the lower undivided, the upper deeply three-lobed, with acuminate lobes, pubeſcent eſpecially on the veins. There is a ſingle gland on the midrib about an inch from the baſe. Petiole half as long again as the leaf, ſpreading very much, thick at the baſe, ſometimes variouſly bent. Stipules in pairs on each ſide of the petiole and peduncle, oblique. Flower ſolitary, commonly one only on each branch: peduncle ſhort, three-ſided, oppoſite to the leaf. The ſtem, branches, petioles, peduncles, young leaves and ſmaller veins of thoſe which are more advanced are dotted with black. The calyx alſo is dotted: the outer three-leaved, and when cloſed three-ſided; the leaflets cordate, laciniated, the ſegments lanceolate, converging: the inner only one-third of the length, urceolate, ſtriated, five-parted, with ſhort, acuminate ſegments. Corolla as large as that of the Holly-hock, white turning red as it withers, without any ſpots at the baſe, where it is hirſute. Piſtil longer than the ſtamens. Stigmas five, hanging down beyond the ſtamens, dotted with black. Capſule ovate-oblong, four-valved, ſometimes but ſeldom five-valved, four-celled ſeldom five-celled. Seeds in each cell four to ſix or more, in a double row, involved in very white cotton[e].
